Question: 1 of 100

A 28-year-old car mechanic is admitted to the hospital having taken an overdose of methanol after splitting up from his wife.

On admission to the emergency department he is drowsy and intoxicated. His BP is 134/82 mmHg, and he has a tachycardia with a pulse of 95.

Investigations show

Haemoglobin	14.0 g/dl	(13.5-17.7)
White cell count	8.1 x 10^9/l	(4-11)
Platelets	190 x 10^9/l	(150-400)
Serum sodium	137 mmol/l	(135-146)
Serum potassium	4.2 mmol/l	(3.5-5)
Bicarbonate	17 mmol/l	(22-30)
Creatinine	130 µmol/l	(79-118)

Which of the following is the most appropriate antidote for methanol poisoning?

(Please select 1 option)

- Atenolol
- Ethanol
- Glucagon

Work Smart Session - MRCP Part 1

Time taken: 19 mins 16 secs

Question: 10 of 100

Which is the predominant site of effect of thiazide diuretics?

(Please select 1 option)

- Cortical collecting duct
- Early distal tubule
- Late distal tubule
- Proximal tubule
- Thick ascending limb, Loop of Henle

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 47 mins 32 secs

Question: 100 of 100

With regard to poisoning / overdose:

(Please select 1 option)

- Phenobarbitone causes a metabolic acidosis
- Ethylene glycol causes a metabolic alkalosis and renal failure
- Aspirin causes acidosis due to hypoventilation
- Methanol causes a metabolic acidosis with an increased anion gap
- Chlormethiazole causes hyperthermia and hypertension

Work Smart Session - MRCP Part 1

Time taken: 20 mins 16 secs

Question: 10 of 100

Which is the predominant site of effect of thiazide diuretics?

(Please select 1 option)

○	Cortical collecting duct
◉	Early distal tubule ✓ Correct
○	Late distal tubule
○	Proximal tubule
○	Thick ascending limb, Loop of Henle

Thiazide diuretics act on the cortical diluting segment of the nephron, predominantly in the early distal tubule.

Loop diuretics mainly act on the thick ascending limb of the Loop of Henle.

Potassium sparing diuretics, for example amiloride, act on the distal nephron.

(For a simplistic review see ABC of heart failure.)

Work Smart Session - MRCP Part 1

Time taken: 20 mins 16 secs

Question: 11 of 100

A 65-year-old man has locally advanced pancreatic cancer and has been paying privately for treatment with erlotinib (Tarceva) for the past nine months. It has worked effectively for that period but a recent CT scan showed further growth in the tumour.

Which of the following mechanisms best explains this resistance to treatment with erlotinib?

(Please select 1 option)

- Development of antibodies to erlotinib
- Lack of autophosphorylation at binding site
- Malabsorption
- Mutated IGF-1 receptor
- Reduced expression of EGFR

Submit answer | Skip question | Remove question

Which of the following mechanisms best explains this resistance to treatment with erlotinib?

(Please select 1 option)

◉	Development of antibodies to erlotinib ✕ Incorrect answer selected
○	Lack of autophosphorylation at binding site
○	Malabsorption
○	Mutated IGF-1 receptor ← This is the correct answer
○	Reduced expression of EGFR

Erlotinib specifically targets the epidermal growth factor receptor tyrosine kinase (which is required for the conformational change) and binds in a reversible fashion to the adenosine triphosphate binding site.

For the signal to be transmitted, two members of the EGFR family need to come together to form a homodimer. These then use the molecule of ATP to autophosphorylate each other, which causes a conformational change in their intracellular structure, exposing a further binding site for binding proteins that cause a signal cascade to the nucleus. By inhibiting the ATP, autophosphorylation is not possible and the signal is stopped.

A key issue with EGFR-directed treatments is that after a period of 8-12 months, the cancer cells become resistant to the treatment, most commonly by recruiting a mutated IGF-1 receptor to act as one of the EGFR partners in the homodimer, so forming a heterodimer. This allows the signal to be transmitted even in the presence of an EGFR inhibitor.

Some IGR-1R inhibitors are in various stages of development (based either around tyrphostins such as AG1024 or AG538 or pyrrolo[2,3-d]-pyrimidine derivatives such as NVP-AEW541.

A 68-year-old lady presented to her general practitioner with a history of generalised tiredness.

She had recently been commenced on a water tablet to ease her swollen feet. She was also diagnosed with glaucoma for which she used topical eye drops.

Investigations:

Serum sodium	138 mmol/L (137-144)
Serum potassium	Haemolysed sample
Serum urea	4.3 mmol/L (2.5-7.5)
Serum creatinine	88 µmol/L (60-110)
Serum corrected calcium	2.68 mmol/L (2.2-2.6)

Which diuretic was this lady most probably taking?

(Please select 1 option)

- Acetazolamide
- Amiloride
- Bendroflumethiazide
- Furosemide
- Indapamide

Work Smart Session - MRCP Part 1

Time taken: 23 mins 34 secs

Question: 13 of 100

A 26-year-old woman was being treated in the outpatient clinic for autoimmune hypothyroidism.

She was taking 150µg of thyroxine and 200 mg of amiodarone.

Investigations reveal:

Plasma prolactin	654 mU/L	(<360)
Plasma free T4	24 pmol/L	(10-22)
Plasma free T3	5.2 pmol/L	(5-10)
Plasma thyroid-stimulating hormone	68 mU/L	(0.4-5)

What is the most likely explanation for her high TSH levels?

(Please select 1 option)

- Amiodarone effect
- Hyperprolactinaemia
- Poor compliance with medications
- Thyroid hormone resistance
- TSH producing pituitary adenoma

Plasma prolactin	654 mU/L	(<360)
Plasma free T4	24 pmol/L	(10-22)
Plasma free T3	5.2 pmol/L	(5-10)
Plasma thyroid-stimulating hormone	68 mU/L	(0.4-5)

What is the most likely explanation for her high TSH levels?

(Please select 1 option)

- Amiodarone effect
- Hyperprolactinaemia
- Poor compliance with medications ✓ Correct
- Thyroid hormone resistance
- TSH producing pituitary adenoma

This young woman has a slightly elevated thyroxine (T4) and an elevated thyroid-stimulating hormone (TSH).

The most probable explanation is poor compliance. This also explains the slightly high prolactin concentration too; a consequence of reduced dopaminergic tone on the lactotrophs.

The typical scenario is that the patients take their medication in the days before the clinic.

This is a classic MRCP question and is highly discriminating. Consider this one carefully and try to understand fully why this is not an effect of amiodarone.

Work Smart Session - MRCP Part 1

Time taken: 26 mins 18 secs

Question: 14 of 100

A 45-year-old obese male with a two year history of type 2 diabetes has recently commenced metformin at a dose of 500 mg twice daily. However, he re-attends clinic and reports numerous gastrointestinal side effects including bloating and flatulence. He is keen to stop metformin and commence an alternative agent.

Which of the following drugs is the most appropriate choice?

(Please select 1 option)

- Acarbose
- Exenatide
- Insulin
- Pioglitazone
- Repaglinide

A 45-year-old obese male with a two year history of type 2 diabetes has recently commenced metformin at a dose of 500 mg twice daily. However, he re-attends clinic and reports numerous gastrointestinal side effects including bloating and flatulence. He is keen to stop metformin and commence an alternative agent.

Which of the following drugs is the most appropriate choice?

(Please select 1 option)

○	Acarbose
○	Exenatide
○	Insulin
○	Pioglitazone ← This is the correct answer
◉	Repaglinide ✕ Incorrect answer selected

An obese type 2 diabetic patient is almost certain to be insulin resistant.

Current guidelines suggest that first line therapy in obese, insulin resistant patients should be an insulin sensitising agent (Bailey C et al. Br J Diabetes Vas Dis 2006; 6: 147-148). Metformin is the drug of choice in this patient therefore.

In patients intolerant of metformin, pioglitazone is licensed for monotherapy for insulin resistant patients. It should however be avoided in patients who have a history of heart failure, because of the risk of fluid retention,and is associated with increased risk of bone fracture.

Work Smart Session - MRCP Part 1

Time taken: 29 mins 23 secs

Question: 15 of 100

A 70-year-old woman is on multiple medications for various conditions and she is found to have a macrocytic anaemia with a low serum B_{12}.

Which of the following medications is a possible cause of the B_{12} deficiency?

(Please select 1 option)

○	Amiodarone
○	Ezetimibe
○	Metformin ← This is the correct answer
○	Nicotinic acid
◉	Sodium valproate ✕ Incorrect answer selected

Metformin can lead to reduced B_{12} absorption but this is not usually a clinical problem.

"The clinician must be aware of the possibility of metformin-associated B_{12} deficiency in users who suffer cognitive impairment, peripheral neuropathy, subacute combined degeneration of the cord or anaemia." Age Ageing. 2006 Mar;35(2):200-1

Work Smart Session - MRCP Part 1

Time taken: 30 mins 10 secs

Question: 16 of 100

A 51-year-old lady enquires about taking hormone replacement therapy (HRT).

Which of the following is the most compelling indication for taking HRT?

(Please select 1 option)

- Control of flushing ← This is the correct answer
- Prevent Alzheimer's disease
- Prevent ischaemic heart disease
- Prevent osteoporosis ✕ Incorrect answer selected
- Reverse vaginal atrophy

The indications for HRT have been a matter of great debate over recent years.

Relieving the symptoms of menopause is the most compelling indication.

Work Smart Session - MRCP Part 1

Time taken: 31 mins 24 secs

Question: 17 of 100

A 23-year-old man with known peanut allergy presented to the Emergency Department with anaphylaxis. He has a swollen face and lips. His BP is 90/60 mmHg, pulse 110 bpm and he is wheezy.

Which of the following formulations of adrenaline should be given?

(Please select 1 option)

○	0.5 ml of 1:10000 adrenaline IM
◉	0.5 ml of 1:1000 adrenaline IM ✓ Correct
○	5 ml of 1:1000 adrenaline IM
○	10 ml of 1:10000 adrenaline IV
○	Nebulised adrenaline

"For adults, a dose of 0.5 mL adrenaline 1:1000 solution (500 micrograms) should be administered intramuscularly, and repeated after about five minutes in the absence of clinical improvement or if deterioration occurs after the initial treatment especially if consciousness becomes - or remains - impaired as a result of hypotension. In some cases several doses may be needed, particularly if improvement is transient."
Resuscitation Council UK.

Adult EpiPen which allergy sufferers can carry with them contains 0.3 mg adrenaline in a 1:1000 dilution for intramuscular (IM) injection.

A 48-year-old lady with a history of epilepsy and ischaemic heart disease presented with the following full blood count.

Haemoglobin	7.4 g/dL	(11.5 - 16.5)
Mean cell volume	125 fL	(80 - 96)
White cell count	2.5 x 10^9/L	(4 - 11)
Platelet count	130 x 10^9/L	(150 - 400)

Which of the following medications is the most likely cause?

(Please select 1 option)

- ○ Carbamazepine
- ○ Clopidogrel
- ○ Furosemide
- ◉ Phenytoin ✓ Correct
- ○ Spironolactone

There is a macrocytic anaemia with low platelets and WCC typical of a nutritional deficiency.

Phenytoin can lead to folate deficiency and is therefore the most likely cause.

Creatinine	130 µmol/l	(79-118)

Which of the following is the most appropriate antidote for methanol poisoning?

(Please select 1 option)

- Atenolol
- Ethanol ✓ Correct
- Glucagon
- Insulin
- Polyethylene glycol

Methanol, like ethanol, is metabolised by alcohol dehydrogenase to form formaldehyde. Formaldehyde is then further metabolised by aldehyde dehydrogenase to formic acid. Formate formation leads to a severe metabolic acidosis, and crystals forming within the eye can lead to so called 'snow field' cataract formation.

Inhibition of metabolism of methanol by alcohol dehydrogenase with either ethanol or fomepizole is the treatment of choice.

Work Smart Session - MRCP Part 1

Time taken: 34 mins 20 secs

Question: 20 of 100

A 50-year-old man presented with a milky discharge from his nipples. He had a history of depression and gastro-oesophageal reflux disease and was on a number of medications.

Plasma prolactin	650 mU/L	(< 360)

Which of the following is the most likely cause of his symptoms?

(Please select 1 option)

- Amitryptiline
- Cimetidine
- Fluoxetine
- Metoclopramide ✓ Correct
- Omeprazole

This man has galactorrhoea and raised prolactin.

The most likely culprit is metoclopramide through its action on dopamine. It releases prolactin through dopamine antagonism.

Time taken: 34 mins 20 secs

Question: 21 of 100

A 60-year-old lady is taking warfarin for stroke prevention in atrial fibrillation.

She presents with a markedly raised INR.

Which of the following medications is the most likely to be the reason?

(Please select 1 option)

- Aspirin
- Carbamazepine
- Ciprofloxacin
- Flucloxacillin
- St John's Wort

Work Smart Session - MRCP Part 1

Time taken: 35 mins 28 secs

Question: 21 of 100

A 60-year-old lady is taking warfarin for stroke prevention in atrial fibrillation.

She presents with a markedly raised INR.

Which of the following medications is the most likely to be the reason?

(Please select 1 option)

○	Aspirin
○	Carbamazepine
○	Ciprofloxacin ← This is the correct answer
○	Flucloxacillin
◉	St John's Wort ✕ Incorrect answer selected

Ciprofloxacin is an inhibitor of p450 and therefore prolongs the half-life of warfarin and raises the international normalised ratio (INR).

Even patients are aware of the increased risk of bleeding with aspirin but it does not have a clear relationship with INR.

Time taken: 35 mins 28 secs

Question: 22 of 100

A 72-year-old lady presented after taking an overdose of a sustained-release propranolol preparation.

She has a pulse of 40 bpm and a BP of 90/60 mmHg.

She was given atropine by the emergency department staff but there has been little response.

Which of the following is the most appropriate treatment?

(Please select 1 option)

- Atropine
- Glucagon
- Haemodialysis
- Noradrenaline
- Salbutamol

Work Smart Session - MRCP Part 1

Time taken: 37 mins

Question: 23 of 100

A 60-year-old man presented with a rash over his forearms, shins and face when he visited cardiology clinic in the summer.

Which of the following medications is the most likely to be associated with this photosensitive rash?

(Please select 1 option)

- Atenolol
- Bendroflumethiazide ✓ Correct
- Clopidogrel
- Digoxin
- Ezetimibe

Photosensitivity is a common adverse effect and the cardiology drugs affected include amiodarone and thiazide diuretics.

Angiotensin-converting enzyme (ACE) inhibitors and angiotensin 2 receptor blockers (A2RBs) commonly cause rashes some of which appear to be photosensitive.

Work Smart Session - MRCP Part 1

Time taken: 37 mins 42 secs

Question: 24 of 100

Which of the following mechanisms best explains the action of simvastatin?

(Please select 1 option)

○	Activates PPAR-alpha
○	Bile acid sequestration
◉	Decreases hepatic cholesterol synthesis ✓ Correct
○	Increases peroxisomal beta-oxidation of fatty acids
○	Inhibits cholesterol absorption

Most circulating cholesterol is manufactured internally, in amounts of about 1000 mg/day, via carbohydrate metabolism through the HMG-CoA reductase pathway.

Statins act by competitively inhibiting HMG-CoA reductase, the first committed enzyme of the HMG-CoA reductase pathway.

Work Smart Session - MRCP Part 1

Time taken: 38 mins 43 secs

Question: 25 of 100

Interferon alpha immunotherapy is used as treatment of which for the following conditions?

(Please select 1 option)

- Acute lymphoblastic leukaemia
- Acute myeloid leukaemia
- Burkitt's lymphoma
- Hairy cell leukaemia ← This is the correct answer
- Myelodysplastic syndrome ✕ Incorrect answer selected

"Interferon-alpha is an immune system hormone which is very helpful to a relatively small number of patients, and somewhat helpful to most patients. Most commonly, the drug helps stabilize the disease or produce a slow, minor improvement. The typical dosing schedule injects 3 million units of Interferon-alpha (not pegylated versions) three times a week, although the original protocol began with six months of daily injections." Wikipedia: Hairy cell leukemia

A 60-year-old man has left ventricular failure and clinically he is classified as NYHA Class III.

He takes furosemide, aspirin and ramipril.

The addition of which one of the following betablockers would be expected further to improve his prognosis?

(Please select 1 option)

○	Acebutolol
◉	Bisoprolol ✓ Correct
○	Esmolol
○	Propranolol
○	Sotalol

Bisoprolol is a highly selective beta(1)-adrenoceptor antagonist.

Administration of bisoprolol to patients with chronic heart failure is associated with increases in left ventricular function and reductions in heart rate; increases in heart rate variability are also seen.

Two major randomised, double-blind, placebo-controlled, multicentre trials have examined the clinical efficacy of bisoprolol in combination with ACE inhibitors and diuretics in patients with stable chronic heart failure (New York Heart Association class III or IV).

An ECG confirms acute myocardial infarction with ST elevation in leads V2-V4 and ST depression in leads II and III.

Which of the following would be a contraindication to thrombolysis in this lady?

(Please select 1 option)

○	History of peptic ulcer disease
◉	Intracranial neoplasm ✓ Correct
○	Menstruation
○	Pre-proliferative diabetic retinopathy
○	Stroke six months previously

Contraindications to thrombolysis include:

- intracranial neoplasm as here
- stroke in the last two months
- pregnancy
- active internal bleeding
- aortic dissection
- recent significant head injury
- severe and uncontrolled hypertension.

Work Smart Session - MRCP Part 1

Time taken: 40 mins 27 secs

Question: 28 of 100

A 17-year-old female presents to the emergency department following self-confessed paracetamol poisoning after discovering she is eight weeks pregnant and had a row with her boyfriend.

She claims to have taken an approximately 30 paracetamol tablets approximately 58 hours ago. Her history is considered to be reliable. There are no abnormalities to find on examination. Her blood sugar by finger prick testing was 3.1 mmol/l.

Which of the following would be the most appropriate treatment for this patient?

(Please select 1 option)

- Haemodialysis
- Intravenous dextrose infusion
- Intravenous N-acetylcysteine
- Oral activated charcoal
- Oral vitamin K

Which of the following would be the most appropriate treatment for this patient?

(Please select 1 option)

○	Haemodialysis
○	Intravenous dextrose infusion
◉	Intravenous N-acetylcysteine ✓ Correct
○	Oral activated charcoal
○	Oral vitamin K

Irrespective of the pregnancy, this girl should receive n-acetyl cysteine.

Paracetamol concentration is unhelpful in delayed presentation of paracetamol overdose. A dose of more than150mg/kg is considered to be toxic and toxicity occurs at a lower concentration if the patient is thought to be in high risk group.

Clotting screen international normalised ratio (INR), liver function tests, acid-base balance and plasma glucose should be taken without delay prior to starting treatment with N-acetylcysteine.

Serial monitoring of clotting screen is required and N-acetylcysteine should continue until INR returns to normal.

Further advice on treatment of complicated cases should be sought from National Poisons Information Service. Other supportive treatment is guided by the patient's condition.

Work Smart Session - MRCP Part 1

Time taken: 41 mins 50 secs

Question: 29 of 100

A 17-year-old boy is admitted with a severe paracetamol overdose following an argument with his girlfriend.

He is treated with intravenous N-acetylcysteine.

Paracetamol is normally metabolised to harmless compounds except in overdose.

Which of the following compounds is the toxic metabolite that accumulates during paracetamol overdose and is reduced by treatment with N-acetylcysteine?

(Please select 1 option)

- Glucuronide
- Homocysteine
- Methionine
- N-acetyl-p-benzoquinoneimine
- N-hydroxyacetaminophen

Paracetamol is normally metabolised to harmless compounds except in overdose.

Which of the following compounds is the toxic metabolite that accumulates during paracetamol overdose and is reduced by treatment with N-acetylcysteine?

(Please select 1 option)

○	Glucuronide
○	Homocysteine
○	Methionine
◉	N-acetyl-p-benzoquinoneimine ✓ Correct
○	N-hydroxyacetaminophen

Paracetamol is predominantly metabolised to glucuronide and sulphate conjugates which are excreted in the urine.

Hepatotoxicity is related to the conversion of a small proportion of the ingested dose to N-acetyl-p-benzoquinoneimine. In therapeutic doses N-acetyl-p-benzoquinoneimine is detoxified by conjugation with glutathione in the liver, but once the protective intracellular glutathione stores are depleted hepatic and renal damage may ensue.

NAC and methionine replenish glutathione stores in the liver and may also act through its sulphhydryl (-SH) group as a direct reducing agent.

Which of the following is most likely to have resulted in her presentation with lithium toxicity?

(Please select 1 option)

○	Amoxicillin
○	Atenolol
○	Paracetamol
◉	Ramipril ✓ Correct
○	Verapamil

ACE inhibitors are known to increase serum lithium levels, as are dihydropyridine calcium antagonists.

Atenolol, in contrast, is a relatively safer option for the treatment of hypertension in association with long term lithium use.

Verapamil in combination with lithium leads to neurotoxicity; this is independent of any increase in serum lithium levels.

If patients have poorly controlled hypertension and they are taking lithium, it may be better to discuss the case with the psychiatrist to see if they can be changed to another mood stabilising agent, such as sodium valproate.

Question: 3 of 100

A 24-year-old IV drug abuser presents with jaw spasm to the emergency department. She says she re-used a heroin needle a few days ago and a couple of her sites look infected.

She has suffered recurrent admissions with pneumonia over the past two years and has been using heroin for the past four years.

On examination she is pyrexial 37.8°C. She has jaw spasm, significant neck stiffness and looks in pain. Examination of her groin and left ante-cubital fossa reveals discharging sinuses from where she has injected heroin previously.

Investigations show

Hb	11.4 g/dl	(13.5-18)
WCC	10.8 x 10^9/l	(4-10)
PLT	179 x 10^9/l	(150-400)
Na	139 mmol/l	(134-143)
K	4.5 mmol/l	(3.5-5)
Cr	129 µmol/l	(60-120)

She is given immunoglobulin.

Which of the following antibiotic treatments is most appropriate in addition?

(Please select 1 option)

- Chloramphenicol
- Ciprofloxacin

Work Smart Session - MRCP Part 1

Time taken: 43 mins 15 secs

Question: 30 of 100

Which of the following are centrally acting antihypertensive therapies?

(Please select 1 option)

- Hydralazine
- Minoxidil
- Moxonidine ✓ Correct
- Phenoxybenzamine
- Verapamil

Moxonidine and alpha-methyl dopa are centrally acting antihypertensives and modify blood pressure through central action modifying sympathetic activity.

Verapamil is a calcium antagonist, minoxidil and hydralazine both vasodilators and phenoxybenzamine an alpha blocker.

(Please select 1 option)

- Amitriptyline
- Gabapentin
- Psychiatric referral
- Ropinirole ✓ Correct
- Venlafaxine

This patient has features of restless legs syndrome (RLS). Typically there is an uncomfortable sensation in the legs and a feeling of needing to move them.

The exact aetiology is unknown. Although no specific tests exist for the diagnosis it is based on the International Restless Legs Syndrome Study Group four basic criteria for diagnosing RLS:

(1) a desire to move the limbs, often associated with paresthesias or dysesthesias

(2) symptoms that are worse or present only during rest and are partially or temporarily relieved by activity

(3) motor restlessness, and

(4) nocturnal worsening of symptoms.

Treatment depends on the severity of the problem and the most appropriate treatment here would be ropinirole, which is the only agent licensed for this purpose.

Work Smart Session - MRCP Part 1

Time taken: 44 mins 26 secs

Question: 32 of 100

A 55-year-old woman who has a history of atrial fibrillation and is receiving warfarin and digoxin informs you that she has been feeling down of late and has been self medicating with St John's wort that she obtained from a health shop.

Which of the following interactions may be expected between St John's wort and her current medication?

(Please select 1 option)

- Digoxin concentrations are unlikely to be affected
- INR is likely to be increased
- INR is likely to be reduced
- INR is likely to be unaffected
- There is an increased risk of digoxin toxicity

Work Smart Session - MRCP Part 1

Time taken: 45 mins 40 secs

Question: 32 of 100

A 55-year-old woman who has a history of atrial fibrillation and is receiving warfarin and digoxin informs you that she has been feeling down of late and has been self medicating with St John's wort that she obtained from a health shop.

Which of the following interactions may be expected between St John's wort and her current medication?

(Please select 1 option)

- Digoxin concentrations are unlikely to be affected
- INR is likely to be increased
- **INR is likely to be reduced** ✓ Correct
- INR is likely to be unaffected
- There is an increased risk of digoxin toxicity

St John's wort is now commonly taken for depressive symptoms, yet it is a liver enzyme inducer and therefore has interactions with medications typically reducing the efficacy.

In this regard St John's wort may reduce the efficacy of warfarin, requiring increased dose to maintain the INR and it may also reduce the efficacy of digoxin.

A 38-year-old woman with a 10 year history of type 1 diabetes attends for annual review.

She has background diabetic retinopathy, microalbuminuria with a urine albumin:creatinine ratio of 4.8 mg/dl (<3). Currently, she takes basal bolus insulin four times daily and lisinopril.

She is a non-smoker, has a BMI of 30 kg/m^2 and a blood pressure of 124/70 mm/hg.

Investigations reveal:

HbA_{1c}	7.3%	(3.8-6.4)
Total cholesterol	5.2 mmol/l	(<5.2)
Triglyceride	1.9 mmol/l	(0.45-1.69)
LDL cholesterol	3.3 mmol/l	(<3.36)
HDL cholesterol	1.3 mmol/l	(>1.55)

Which would be the most appropriate treatment for this patient's lipid profile?

(Please select 1 option)

- Ezetimibe
- Fenofibrate
- No treatment required
- Omega-3 fatty acids
- Simvastatin

Omega-3 fatty acids	✗ Incorrect answer selected
Simvastatin	← This is the correct answer

Type 1 diabetes after a duration of 10 years is associated with a 2% annual coronary heart disease (CHD) event rate, while the risk of cardiovascular events is increased in people with type 1 diabetes by factors such as co-existing microvascular complications, in particular nephropathy.

Furthermore female gender is associated with an approximate twofold increase in relative cardiovascular disease (CVD) risk in type 1 diabetes, while other factors associated with increased CVD risk in type 1 diabetes include:

- Degree of glycaemia
- Duration of diabetes

as well as classically recognised factors such as

- Hypertension
- Dyslipidaemia.

The most recent CVD treatment guidelines JBS-2 advocate that treatment targets for low density lipoprotein-cholesterol (LDL-C) and total cholesterol (TC) of <2 and <4 mmol/l in all people with diabetes over the age of 40 years, and in those under 40 where there are co-existing risk factors, for example:

- Poor glycaemic control (Hba_{1c} >9%)
- Co-existing microvascular complications
- Presence of another CVD risk factor or
- Features of the metabolic syndrome (NCEP ATP III).

Therefore in this case simvastatin would be the most appropriate treatment choice, aiming for a treatment TC <4 mmol/l.

Statins are however not licensed for use in pregnancy, and women of child bearing age need to be counselled regarding pregnancy issues when initiating stain therapy.

Repeat lipid profile is recommended eight weeks following initiation of therapy to enable any therapeutic adjustments to be made.

Work Smart Session - MRCP Part 1

Time taken: 48 mins 19 secs

Question: 34 of 100

A 25-year-old female is diagnosed with polycystic ovarian syndrome and commenced on metformin.

Which of the following are recognised effects of the use of metformin in the treatment of polycystic ovarian syndrome?

(Please select 1 option)

- Improves action of vasopressin
- Improves chances of conception
- Increases exercise capacity
- Reduces testosterone concentration
- Reduces weight

Work Smart Session - MRCP Part 1

Time taken: 49 mins 20 secs

Question: 34 of 100

A 25-year-old female is diagnosed with polycystic ovarian syndrome and commenced on metformin.

Which of the following are recognised effects of the use of metformin in the treatment of polycystic ovarian syndrome?

(Please select 1 option)

- Improves action of vasopressin
- Improves chances of conception ✓ Correct
- Increases exercise capacity
- Reduces testosterone concentration
- Reduces weight

Polycystic ovarian syndrome is recognised to be a condition associated with increased insulin resistance and metformin is effective through improvements in insulin sensitivity resulting in ovulation and improvements in hormonal perturbations.

It has been shown to increase rates of conception but has no appreciable effect on weight loss.

Work Smart Session - MRCP Part 1

Time taken: 50 mins 28 secs

Question: 35 of 100

A 57-year-old woman develops a blistering rash around the midriff and is diagnosed with *Herpes zoster*. She is treated with acyclovir.

Which of the following is responsible for the activation of acyclovir?

(Please select 1 option)

○	Integrase
◉	Polymerase ✗ Incorrect answer selected
○	Protease
○	Reverse transcriptase
○	Thymidine kinase ← This is the correct answer

This is a variation on the acyclovir theme.

Acyclovir acts through inhibition of viral deoxyribonucleic acid (DNA) polymerase but it is a pro-hormone and first requires phosphorylation by thymidine kinase.

Work Smart Session - MRCP Part 1

Time taken: 50 mins 28 secs

Question: 36 of 100

A 25-year-old female who is 20 weeks pregnant with her first child is admitted with palpitations.

The ECG reveals a supraventricular tachycardia (SVT) and this self terminates 20 minutes after admission. Subsequently she has further runs of symptomatic SVT.

What would be the most appropriate treatment for this patient's paroxysmal supraventricular tachycardia?

(Please select 1 option)

- Amiodarone
- Disopyramide
- Flecainide
- Metoprolol
- Verapamil

A 25-year-old female who is 20 weeks pregnant with her first child is admitted with palpitations.

The ECG reveals a supraventricular tachycardia (SVT) and this self terminates 20 minutes after admission. Subsequently she has further runs of symptomatic SVT.

What would be the most appropriate treatment for this patient's paroxysmal supraventricular tachycardia?

(Please select 1 option)

○	Amiodarone
○	Disopyramide
○	Flecainide
○	Metoprolol ← This is the correct answer
◉	Verapamil ✕ Incorrect answer selected

Tachyarrhythmias may increase during pregnancy although the causes are not entirely clear.

Regarding the termination of acute SVT, adenosine appears to be safe in pregnancy. In the case of the prevention of recurrent SVT then verapamil or beta-blockers have data supporting their use.

Current AHA/EHA criteria for the treatment of SVTs in pregnancy do suggest using metoprolol (level of evidence 1B) rather than verapamil (C), although they recommend avoiding the former in the first trimester.

Work Smart Session - MRCP Part 1

Time taken: 51 mins 37 secs

Question: 37 of 100

A patient is referred to the hepatology department for possible treatment of hepatitis B.

He has stigmata of chronic liver disease. There is portal hypertension and ascites. His INR is 2.2 (<1.4) and albumin 25 g/L (37-49). HBsAg and HBeAg positive. Hepatitis C screen is negative.

What will you suggest for treatment?

(Please select 1 option)

- Beta interferon
- Lamivudine alone
- Lamivudine plus interferon
- Ribavarin alone
- Ribavarin plus interferon

Work Smart Session - MRCP Part 1

Time taken: 52 mins 55 secs

Question: 37 of 100

A patient is referred to the hepatology department for possible treatment of hepatitis B.

He has stigmata of chronic liver disease. There is portal hypertension and ascites. His INR is 2.2 (<1.4) and albumin 25 g/L (37-49). HBsAg and HBeAg positive. Hepatitis C screen is negative.

What will you suggest for treatment?

(Please select 1 option)

○	Beta interferon
◉	Lamivudine alone ✓ Correct
○	Lamivudine plus interferon
○	Ribavarin alone
○	Ribavarin plus interferon

Interferon cannot be used in this case as it can initially worsen hepatic decompensation.

Lamivudine alone is safe in decompensated hepatitis B virus (HBV) infection.

Ribavirin is used for hepatitis C infection. Its combination with interferon confers more success in treating HCV infection.

What is the immediate management for this patient?

(Please select 1 option)

- Carbimazole
- DC cardioversion
- Digoxin
- **Propanolol** ✓ Correct
- Warfarin

AF occurs in 10% to 25% of patients with hyperthyroidism, more commonly in men and the elderly than in women or patients less than 75 years old.

In a patient with hyperthyroidism and AF, initial therapy should focus on ventricular rate control with β-blockers, but conversion to sinus rhythm frequently occurs spontaneously with treatment of hyperthyroidism.

AF in thyrotoxicosis is characterised by rapid ventricular response, typically resistant to digoxin therapy.

Electric or pharmacologic cardioversion should be attempted only in euthyroid patients who are haemodynamically unstable.

If AF persists, consideration should be given to anticoagulation in patients who are at risk of embolic events.

Work Smart Session - MRCP Part 1

Time taken: 56 mins 44 secs

Question: 39 of 100

An elderly asthmatic lady on treatment with high dose prednisolone complains of a four week history of right hip pain.

She comments that recently she seems to be developing more facial hair and adds that she has also been diagnosed with high blood pressure and diabetes.

On examination she is noted to be unable to weight bear on the right side.

What is the most likely cause of her hip pain?

(Please select 1 option)

- Avascular necrosis of femoral head
- Dislocation of the hip joint
- Fracture neck of femur
- Gout
- Osteoarthritis of the hip joint

An elderly asthmatic lady on treatment with high dose prednisolone complains of a four week history of right hip pain.

She comments that recently she seems to be developing more facial hair and adds that she has also been diagnosed with high blood pressure and diabetes.

On examination she is noted to be unable to weight bear on the right side.

What is the most likely cause of her hip pain?

(Please select 1 option)

◉	Avascular necrosis of femoral head ✓ Correct
○	Dislocation of the hip joint
○	Fracture neck of femur
○	Gout
○	Osteoarthritis of the hip joint

This question simply tests the knowledge of side effects of corticosteroids (a favourite theme in MRCP 1).

The patient has features of hypercortisolism.

Obviously avascular necrosis of femoral head is the cause of her right hip pain.

K	4.5 mmol/l	(3.5-5)
Cr	129 µmol/l	(60-120)

She is given immunoglobulin.

Which of the following antibiotic treatments is most appropriate in addition?

(Please select 1 option)

- ◉ Chloramphenicol ✕ Incorrect answer selected
- ○ Ciprofloxacin
- ○ Erythromycin
- ○ Metronidazole ← This is the correct answer
- ○ Oxytetracycline

This woman is suffering from tetanus as a result of infection via a contaminated drug injecting needle.

Initial management of choice is anti-tetanus immunoglobulin, followed in this case by the addition of systemic antibiotics, either metronidazole or benzylpenicillin, and debridement of any wound if required.

Diazepam, neuromuscular blockade, and intubation may all be required during the acute phase.

Over the longer term, muscle spasms and ankle clonus can persist for many months.

A 70-year-old man is admitted with pruritus, jaundice and a 2 kg weight loss of two weeks duration.

He had not drunk any alcohol for at least eight years.

One month ago, he had completed a course of co-amoxiclav which had been prescribed by his GP for sinusitis and he was also taking ibuprofen for hip osteoarthritis.

Investigations reveal:

Albumin	38 g/l	(37-49)
Bilirubin	200 mol/l	(1-22)
AST	200 U/l	(5-35)
Alkaline phosphatase	200 U/l	(45-105)

Abdominal ultrasound reveals gallstones but no biliary duct dilatation.

What is the most likely cause of his jaundice?

(Please select 1 option)

- Cholangio-carcinoma
- Co-amoxiclav
- Hepatitis B infection
- Hepatitis C infection
- Ibuprofen

Work Smart Session - MRCP Part 1

Time taken: 59 mins 41 secs

Question: 40 of 100

Which term best describes the affinity of a drug for its receptor?

(Please select 1 option)

- Efficacy
- Intrinsic activity
- Potency ✓ Correct
- Selectivity
- Therapeutic effect

Affinity is the measure of the net molecular attraction between a drug (or neurotransmitter or hormone) and its receptor.

The receptor's affinity for binding a drug determines the concentration of drug required to form a significant number of drug-receptor complexes.

Affinity and intrinsic activity are determinants of potency.

Efficacy contributes both to potency and to the maximum effect of the agonist. Efficacy is a measure of the efficiency of the drug-receptor complex in initiating the signal transduction process.

○	Insulin higher, glucose higher in Route A
◉	Insulin higher, glucose higher in Route B ✕ Incorrect answer selected
○	Insulin higher, glucose lower in Route A
○	Insulin higher, glucose lower in Route B ← This is the correct answer

Glucose given via the gut elicits a greater insulin response as compared to the same quantity given intravenously even though the plasma glucose peak is higher when it is given IV. This phenomenon is called the 'incretin effect'.

The incretin effect denominates the phenomenon that oral glucose elicits a higher insulin response than does intravenous glucose.

The two hormones responsible for the incretin effect, glucose-dependent insulinotropic hormone (GIP) and glucagon-like peptide-1 (GLP-1), are secreted after oral glucose loads and augment insulin secretion in response to hyperglycaemia.

Gastric Inhibitory Polypeptide and Glucagon-Like Peptide-1 in the Pathogenesis of Type 2 Diabetes. Diabetes 53:S190-S196, 2004

The investigation of the incretin effect is not usually performed using the same quantity of glucose as in this question. An 'isoglycaemic study' is often used where an infusion of glucose is designed to copy exactly the blood glucose profile generated in an individual or animal by a certain enteral glucose load.

Exenatide (synthetic exendin-4) is a new agent for the treatment of type 2 diabetes. Exendin-4 occurs naturally in the saliva venom of the [illegible] American lizard called the Gila Monster. It mimics the action of the gut hormone GLP-1 (Glucagon-like peptide 1).

Which drug is the most likely to have caused this reaction?

(Please select 1 option)

◉	Aspirin ✓ Correct
○	Glyceryl trinitrate
○	Omeprazole
○	Paracetamol
○	Simvastatin

The most likely cause of an urticarial eruption from this list would be aspirin.

Other drugs frequently associated with urticaria include

- Non-steroidal anti-inflammatory drugs (NSAIDs)
- Penicillin
- Angiotensin-converting enzyme (ACE) inhibitors
- Thiazides
- Codeine.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 4 mins 5 secs

Question: 43 of 100

A 21-year-old man, who has a past history of IV drug abuse, presents 12 hours after taking an overdose of 480 mg of codeine and 30 g of paracetamol.

His blood pressure is 100/60 mmHg and he has pin-point pupils.

What is the most appropriate management for this patient?

(Please select 1 option)

- ○ 500ml 10% glucose IV over four hours
- ○ 1 litre normal saline IV over six hours
- ○ IV naloxone
- ○ IV flumazenil
- ○ Start N-acetylcysteine

paracetamol.

His blood pressure is 100/60 mmHg and he has pin-point pupils.

What is the most appropriate management for this patient?

(Please select 1 option)

○	500ml 10% glucose IV over four hours
○	1 litre normal saline IV over six hours
○	IV naloxone
◉	IV flumazenil ✕ Incorrect answer selected
○	Start N-acetylcysteine ← This is the correct answer

This patient presents 12 hours after taking a potentially fatally toxic dose of paracetamol.

In the circumstances provided in this question where there is an absence of data relating to pulse rate (as he is probably not in shock), respiratory rate (reflecting respiratory depression) or blood glucose, the most appropriate intervention at this 12 hour time-point would be N-acetylcysteine.

The urgency of treatment is underlined by the fact that the incidence of hepatotoxicity is worse if treatment is delayed.

Trials of N-acetylcysteine suggest that the incidence of hepatotoxicity is 1% in those treated within eight hours versus 46% in those treated after 16 hours.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 6 mins 24 secs

Question: 44 of 100

Which of the following most accurately describes the mechanism of action of the bisphosphonates?

(Please select 1 option)

- Calcium resorption in the distal tubule
- Fibroblast proliferation in bone marrow
- Improved vascular supply to bone marrow
- Inhibition of osteoclast activity ✓ Correct
- Upregulation of osteoblast activity

The mechanism of action of alendronate and risedronate as well as newer agents involves the inhibition of the pathway that leads to the production of certain essential lipid compounds inside osteoclasts.

This results in a series of events leading to decreased osteoclast activity and to the induction of cell death.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 7 mins 19 secs

Question: 45 of 100

A 57-year-old male with diabetes requests sildenafil for erectile dysfunction.

Which of the following are contraindicated with sildenafil?

(Please select 1 option)

○	Carbamazepine
○	Carvedilol
○	Indomethacin
○	Nicorandil ← This is the correct answer
◉	Valsartan ✕ Incorrect answer selected

Sildenafil is contraindicated if the patient is taking nitrates, or nitrate derivatives (nicorandil).

We are informed on the prescribing information that if the patient takes nitrates then they should be stopped for the period during which sildenafil is used.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 7 mins 19 secs

Question: 46 of 100

An 82-year-old male with longstanding Alzheimer's dementia presents as his carers are concerned about his increased episodes of aggression. Physically he is well.

Which is the most appropriate treatment for his aggressive outbursts?

(Please select 1 option)

- Diazepam
- Quetiapine
- Risperidone
- Temazepam
- Valproate

An 82-year-old male with longstanding Alzheimer's dementia presents as his carers are concerned about his increased episodes of aggression. Physically he is well.

Which is the most appropriate treatment for his aggressive outbursts?

(Please select 1 option)

○	Diazepam
○	Quetiapine ← This is the correct answer
◉	Risperidone ✕ Incorrect answer selected
○	Temazepam
○	Valproate

Risperidone used to be a favourite treatment for aggression/agitation in dementia but recent studies indicate that it is associated with an increased mortality and a threefold increased risk of stroke.

Valproate is widely used for its calming effects in this situation but although widely used there is little evidence of the efficacy of valproate.

Valproic acid for agitation in dementia Cochrane Database Syst Rev. 2004;(2):CD003945

Haloperidol may be associated with cardiac arrhythmias, and its use is now discouraged for long term use.

The other options are associated with more prominent adverse effects.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 8 mins 18 secs

Question: 47 of 100

An 82-year-old lady had a history of a red facial rash and has suffered with venous eczema of the legs. She was treated for acne rosacea.

On examination, she was noted to have blue-grey discolouration of both legs.

What drug is most likely to have caused this?

(Please select 1 option)

- Amiodarone
- Ciprofloxacin
- Doxycycline
- Minocycline
- Oxytetracycline

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 9 mins 49 secs

Question: 47 of 100

An 82-year-old lady had a history of a red facial rash and has suffered with venous eczema of the legs. She was treated for acne rosacea.

On examination, she was noted to have blue-grey discolouration of both legs.

What drug is most likely to have caused this?

(Please select 1 option)

○	Amiodarone
○	Ciprofloxacin
○	Doxycycline
◉	Minocycline ✓ Correct
○	Oxytetracycline

This patient has developed skin pigmentation in her venous eczema due to treatment of her acne rosacea.

Tetracyclines are the most appropriate treatment of acne rosacea and the most likely of these to cause this bluish grey skin pigmentation in the legs is minocycline.

Work Smart Session - MRCP Part 1

Time taken:

Question: 1 of 47

A patient post retrosternal thyroidectomy resection has sudden onset shortness of breath.

On examination, she is talking clearly but has decreased breath sounds on her right side with increased resonance. Her blood pressure is 110/80 mmHg, pulse 95 beats per minute, respiratory rate 24/min and SpO_2 92 on air.

Which of the following would be most appropriate for her?

(Please select 1 option)

- Chest x ray
- Furosemide 40 mg intravenously
- Intercostal chest drain insertion
- Needle thoracocentesis
- Removal of surgical clips

Work Smart Session - MRCP Part 1

Time taken: 14 mins 45 secs

Question: 10 of 47

Which of the following statements regarding the subclavian vein and its relations is correct?

(Please select 1 option)

- Begins at the lateral border of the first rib
- Forms the axillary vein
- Joins the superior vena cava
- The subclavian vein and internal jugular vein form the brachiocephalic trunk
- The subclavian vein passes posterior to scalenus anterior.

Work Smart Session - MRCP Part 1

Time taken: 16 mins 8 secs

Question: 10 of 47

Which of the following statements regarding the subclavian vein and its relations is correct?

(Please select 1 option)

◉	Begins at the lateral border of the first rib ✓ Correct
○	Forms the axillary vein
○	Joins the superior vena cava
○	The subclavian vein and internal jugular vein form the brachiocephalic trunk
○	The subclavian vein passes posterior to scalenus anterior.

The subclavian vein is a continuation of the axillary vein, beginning at the lateral border of the first rib.

It passes anterior to scalenus anterior.

The subclavian and internal jugular vein unite to form the brachiocephalic vein, subsequently the left and right brachiocephalic veins unite to form the superior vena cava.

The brachiocephalic trunk is a branch of the aortic arch, which divides to form the right subclavian and right common carotid arteries.

Work Smart Session - MRCP Part 1

Time taken: 16 mins 8 secs

Question: 11 of 47

A 54-year-old obese male with a history of angina and hypertension presents with central crushing chest pain of two hours duration.

High flow oxygen, sublingual GTN and aspirin are administered and venous access is obtained. Whilst being attached to an ECG monitor he collapses and the initial rhythm is pulseless ventricular tachycardia (VT).

Which of the following is the most appropriate immediate treatment for this man?

(Please select 1 option)

- A ventilation to compression ratio of 30:2 should commenced
- Continuous chest compressions should be started
- He should be defibrillated with a 200 J (monophasic) shock
- He should be given a praecordial thump
- Intravenous adrenaline should be given

High flow oxygen, sublingual GTN and aspirin are administered and venous access is obtained. Whilst being attached to an ECG monitor he collapses and the initial rhythm is pulseless ventricular tachycardia (VT).

Which of the following is the most appropriate immediate treatment for this man?

(Please select 1 option)

○	A ventilation to compression ratio of 30:2 should commenced
○	Continuous chest compressions should be started
◉	He should be defibrillated with a 200 J (monophasic) shock ✕ Incorrect answer selected
○	He should be given a praecordial thump ← This is the correct answer
○	Intravenous adrenaline should be given

An initial praecordial thump is indicated and is more likely to be successful in converting pulseless VT to sinus rhythm, than if the rhythm was ventricular fibrillation (VF).

The appropriate compression to ventilation ratio is 30:2, which should be synchronised to allow effective ventilation, until a laryngeal mask airway (LMA) or tracheal tube is passed.

When using a monophasic defibrillator all unsynchronised shocks are 360 J.

The first dose of adrenaline is given immediately before the third 360 J (monophasic) shock.

Work Smart Session - MRCP Part 1

Time taken: 18 mins 5 secs

Question: 12 of 47

A 78-year-old male who presents with increasing dysphagia is diagnosed with an inoperable carcinoma of the distal oesophagus. Oesophageal spasm causes food to stick after swallowing which causes odynophagia.

Which drug would be most helpful in relieving his chronic pain?

(Please select 1 option)

- Clodronate
- Dexamethasone
- Nifedipine
- Oxybutynin
- Pinaverium

Work Smart Session - MRCP Part 1

Time taken: 19 mins 18 secs

Question: 12 of 47

A 78-year-old male who presents with increasing dysphagia is diagnosed with an inoperable carcinoma of the distal oesophagus. Oesophageal spasm causes food to stick after swallowing which causes odynophagia.

Which drug would be most helpful in relieving his chronic pain?

(Please select 1 option)

○	Clodronate
○	Dexamethasone
◉	Nifedipine ✓ Correct
○	Oxybutynin
○	Pinaverium

Nifedipine helps relieve painful oesophageal spasm and tenesmus associated with gastrointestinal tumours and could be used to relieve his odynophagia.

Clodronate inhibits osteoclastic bone resorption and is used to treat malignant bone pain and the associated hypercalcaemia.

Pinaverium is used to reduce the pain duration associated with irritable bowel syndrome (IBS).

Corticosteroids are used to treat pain from central nervous system tumours and painful bladder spasm may be relieved by oxybutynin.

Work Smart Session - MRCP Part 1

Time taken: 19 mins 18 secs

Question: 13 of 47

A 56-year-old man diagnosed with systemic inflammatory response syndrome (SIRS) secondary to pneumonia is admitted to the high dependency unit.

On examination, he has a temperature of 39°C, a respiratory rate of 30/min, has a pulse of 109 beats/min and a blood pressure of 89/74 mmHg, despite receiving IV fluids and urine output of 25 ml/hour after catheterisation.

Which of the following should be instituted immediately and should be accomplished within the first six hours of presentation?

(Please select 1 option)

- Administer drotrecogin alfa (activated Protein C)
- Administer intravenous furosemide
- Administer low dose steroids
- Institute tight glucose control
- Obtain blood cultures prior to antibiotic administration

○	Institute tight glucose control
○	Obtain blood cultures prior to antibiotic administration ← This is the correct answer

The Surviving Sepsis Campaign (a partnership of the Society of Critical Care Medicine, the European Society of Intensive Care Medicine, and the International Sepsis Forum) has teamed up with the Institute for Healthcare Improvement to develop severe sepsis bundles. A 'bundle' is a group of interventions related to a disease process that, when executed together, result in better outcomes than when implemented individually.

Sepsis Resuscitation Bundle
(Should begin immediately, but must be accomplished within the first six hours of presentation.)

1. Serum lactate measured.
2. Blood cultures obtained prior to antibiotic administration.
3. From the time of presentation, broad-spectrum antibiotics administered within three hours for ED admissions and one hour for non-ED ICU admissions.
4. In the event of hypotension and/or lactate > 4 mmol/l (36 mg/dl):
   - Deliver an initial minimum of 20 ml/kg of crystalloid (or colloid equivalent).
   - Apply vasopressors for hypotension not responding to initial fluid resuscitation to maintain mean arterial pressure (MAP) > 65 mm Hg.
5. In the event of persistent hypotension despite fluid resuscitation (septic shock) and/or lactate > 4 mmol/l (36 mg/dl):
   - Achieve central venous pressure (CVP) of > 8 mm Hg.
   - Achieve central venous oxygen saturation (ScvO2) of > 70%.

Sepsis Management Bundle
(To be accomplished as soon as possible may be completed within twenty-four hours of presentation.)

1. Low-dose steroids administered for septic shock in accordance with a standardised ICU policy.
2. Drotrecogin alfa (activated) administered in accordance with a standardised ICU policy.
3. Glucose control maintained > lower limit of normal, but < 150 mg/dl (8.3 mmol/l).
4. Inspiratory plateau pressures maintained < 30 cm H_2O for mechanically ventilated patients.

Work Smart Session - MRCP Part 1

Time taken: 22 mins 18 secs

Question: 14 of 47

A 47-year-old man presents with progressive right hand swelling two days after being bitten by a dog.

On examination there is a puncture wound with pus over the dorsum of the hand, cellulitis, ascending lymphangitis and tender axillary lymphadenopathy.

What is the most appropriate antibiotics therapy in this case?

(Please select 1 option)

- Benzylpenicillin and flucloxacillin
- Ceftriaxone
- Ciprofloxacin
- Co-amoxiclav
- Erythromycin

Question: 14 of 47

A 47-year-old man presents with progressive right hand swelling two days after being bitten by a dog.

On examination there is a puncture wound with pus over the dorsum of the hand, cellulitis, ascending lymphangitis and tender axillary lymphadenopathy.

What is the most appropriate antibiotics therapy in this case?

(Please select 1 option)

- Benzylpenicillin and flucloxacillin ✕ Incorrect answer selected
- Ceftriaxone
- Ciprofloxacin
- Co-amoxiclav ← This is the correct answer
- Erythromycin

Only 15-20% of dog bites become infected, and providing the wound is appropriately cleaned and not considered at risk (for example, crush or deep wounds) then antibiotic prophylaxis may not be required.

However, this patient has an infected wound, and infective organisms include *Pasteurella* spp, *Staph. aureus* and anaerobes like *Corynebacterium*.

The most appropriate antibiotic therapy in dog bites associated with cellulitis would be co-amoxiclav.

Work Smart Session - MRCP Part 1

Time taken: 23 mins 16 secs

Question: 15 of 47

A 27-year-old female with adult respiratory distress syndrome (ARDS) is ventilated on intensive care.

Her inspired oxygen is 100%, positive end expiratory pressure is 15 cmH_20 and peak airway pressure is 40 cmH2O.

Her arterial blood gas shows:

PaO_2	6 kPa (11.3-12.6)
$PaCO_2$	6.9 kPa (4.7-6.0)
SpO_2	88% (>92%)

Which further ventilatory strategy is appropriate in this case?

(Please select 1 option)

- ○ High frequency oscillatory ventilation (HFOV)
- ○ Increasing tidal volume and respiratory rate on the ventilator
- ○ Inhaled nitric oxide therapy
- ○ Intravenous oxgenation (IVOX)
- ○ Prone position

Which further ventilatory strategy is appropriate in this case?

(Please select 1 option)

○	High frequency oscillatory ventilation (HFOV)
○	Increasing tidal volume and respiratory rate on the ventilator
○	Inhaled nitric oxide therapy
◉	Intravenous oxgenation (IVOX) ✕ Incorrect answer selected
○	Prone position ← This is the correct answer

This lady is on maximal ventilatory therapy but is still hypoxic.

Her high CO_2 is a reflection of permissive hypercapnia to prevent overdistension of the lungs with high tidal volumes.

None of the therapies above are proven to improve mortality. However proning a patient in this situation will improve ventilation/perfusion mismatch and temporarily improve oxygenation.

Some clinicians would move immediately to HFOV without proning as placing a patient face down is obviously fraught with difficulty.

IVOX is complicated and requires specialist equipment and is not proven.

Nitric oxide therapy to improve hypoxic pulmonary vasoconstriction is used infrequently.

Work Smart Session - MRCP Part 1

Time taken: 25 mins 19 secs

Question: 16 of 47

A 67-year-old male is admitted with central chest pain of sudden onset which radiates through to his back.

His blood pressure is 160/70 mmHg in his right arm and 140/60 mmHg in his left arm. He has electrocardiographic (ECG) changes in leads II, III and AVF showing ST elevation of 2 mm.

What is the most likely diagnosis?

(Please select 1 option)

- Coarctation of the aorta
- Dissecting thoracic aortic aneurysm
- Inferior myocardial infarct
- Pancreatitis
- Perforated duodenal ulcer

A 67-year-old male is admitted with central chest pain of sudden onset which radiates through to his back.

His blood pressure is 160/70 mmHg in his right arm and 140/60 mmHg in his left arm. He has electrocardiographic (ECG) changes in leads II, III and AVF showing ST elevation of 2 mm.

What is the most likely diagnosis?

(Please select 1 option)

○	Coarctation of the aorta
◉	Dissecting thoracic aortic aneurysm ✓ Correct
○	Inferior myocardial infarct
○	Pancreatitis
○	Perforated duodenal ulcer

This history is suggestive of a dissecting thoracic aortic aneurysm.

The ECG changes of inferior myocardial infarct suggest that the aneurysm has dissected the right coronary artery at its ascending aortic ostium. An ascending aortic dissection needs immediate surgery. Whilst en route to surgery, beta-blockade to control hypertension is appropriate.

An inferior myocardial infarct is high in the differential - however thrombolysis will kill a patient with an aortic dissection.

Coarctation can give different blood pressures in either arm but is a chronic condition. Ulcer and pancreatitis may mimic a heart attack, but with a normal ECG.

Work Smart Session - MRCP Part 1

Time taken: 27 mins 37 secs

Question: 17 of 47

A 21-year-old male is admitted with acute onset headache and is drowsy. He is opening his eyes spontaneously, is disoriented and is localising painful stimuli. He has a normal computed tomography scan.

Which of the following is the next most appropriate investigation for this patient?

(Please select 1 option)

○	Cerebral angiography
○	Lumbar puncture ← This is the correct answer
○	Magnetic resonance angiography
○	Magnetic resonance imaging
◉	No further investigations necessary ✕ Incorrect answer selected

Lumbar puncture is not usually required unless the history is suggestive and the CT is normal as in this case. Blood will be present in the cerebral spinal fluid (CSF) (if a bloody tap is suspected the number of red blood cells should fall with each successive sample).

If the lumbar puncture (LP) is performed six hours after onset of symptoms the supernatant fluid should be examined for xanthochromia after centrifugation.

A 21-year-old male is admitted with severe acute onset headache. He is disoriented and drowsy and has neck stiffness. Investigations suggest a diagnosis of subarachnoid haemorrhage (SAH).

What grade of SAH does this patient have?

(Please select 1 option)

○	Grade one
○	Grade two
○	Grade three ← This is the correct answer
◉	Grade four ✕ Incorrect answer selected
○	Grade five

This gentleman's history is suggestive of subarachnoid haemorrhage (SAH). The Hunt and Hess scale grades SAH thus:

1. Asymptomatic or minimal headache + slight neck stiffness.
2. Moderate or severe headache with neck stiffness, but no neurological deficit other than cranial nerve palsy.
3. Drowsiness with confusion or mild focal neurology.
4. Stupor with moderate to severe hemiparesis or mild decerebrate rigidity.
5. Deeply comatose with severe decerebrate rigidity.

Severity and mortality increase with grade.

A patient post retrosternal thyroidectomy resection has sudden onset shortness of breath.

On examination, she is talking clearly but has decreased breath sounds on her right side with increased resonance. Her blood pressure is 110/80 mmHg, pulse 95 beats per minute, respiratory rate 24/min and SpO_2 92 on air.

Which of the following would be most appropriate for her?

(Please select 1 option)

○	Chest x ray ← This is the correct answer
○	Furosemide 40 mg intravenously
○	Intercostal chest drain insertion
◉	Needle thoracocentesis ✕ Incorrect answer selected
○	Removal of surgical clips

According to the scenario above this lady has a pneumothorax.

She is not in extremis (suggesting a tension pneumothorax) so needle thoracocentesis is not required.

The history and examination are suggestive of a pneumothorax and therefore, with her being relatively stable, the most appropriate first step would be confirmation with chest x ray followed by chest drain insertion.

Furosemide would not help.

Work Smart Session - MRCP Part 1

Time taken: 2 mins 48 secs

Question: 2 of 47

A 26-year-old female is admitted to ICU with severe asthma.

She is ventilated for one week, and receives IV co-amoxiclav/clarithromycin, magnesium, prednisolone, sedatives and muscle relaxants.

She improves gradually but two days after stopping muscle relaxants she still is unable to be weaned from ventilatory support.

On examination, she is alert but has flaccid weakness of all limbs.

Which of the following is the likely diagnosis?

(Please select 1 option)

- Critical illness polyneuropathy
- Guillain-Barré syndrome
- Hypermagnesaemia
- Prolonged neuromuscular blockade
- Steroid induced myopathy

Work Smart Session - MRCP Part 1

Time taken: 29 mins 12 secs

Question: 20 of 47

An 18-year-old male is admitted with a history of diarrhoea and vomiting associated with weakness and lethargy.

His motor power in the distal arms and legs is decreased and he describes difficulty swallowing. His forced vital capacity (FVC) is 1.5 litres.

Which of the following is the most appropriate immediate treatment for this condition?

(Please select 1 option)

- Cyclophosphamide
- Intravenous immunoglobulin therapy (IgG) 0.5 g/kg
- Intubation and ventilation
- Plasmapheresis
- Prednisolone 60 mg

Which of the following is the most appropriate immediate treatment for this condition?

(Please select 1 option)

○	Cyclophosphamide
○	Intravenous immunoglobulin therapy (IgG) 0.5 g/kg ← This is the correct answer
○	Intubation and ventilation
◉	Plasmapheresis ✕ Incorrect answer selected
○	Prednisolone 60 mg

This scenario is suggestive of Guillain-Barre Syndrome (GBS).

Dysphagia is a dangerous symptom suggestive of bulbar involvement. However a FVC of 1.5 litres is not an indication for immediate ventilation (less than 1 litre is.)

First line therapy is intravenous IgG.

Plasmapheresis can also be used but requires specialist equipment.

Steroids are of no benefit.

Cyclophosphamide although an immune suppressant is a red herring.

Work Smart Session - MRCP Part 1

Time taken: 31 mins 14 secs

Question: 21 of 47

A 66-year-old male in intensive care who is receiving an escalating noradrenaline infusion (currently at 0.76 mcg/kg/min), has a blood pressure of 90/50 mmHg, pulse of 90 beats per min, a central venous pressure of 10mmHg, capillary refill time of 2-3 seconds has received 2000 mls of colloid in 3 hours. His plasma lactate concentration is 2.9 mmol/l (<1.5).

Which of the following is an appropriate method of measuring adequate intravascular filling?

(Please select 1 option)

- ○ LiDCO (lithium dilution cardiac output)
- ○ Oesophageal Doppler monitoring
- ○ PiCCO (pulse contour cardiac output)
- ○ Pulmonary artery flotation catheter (PAFC)
- ○ Transoesophageal echocardiography (TOE)

colloid in 3 hours. His plasma lactate concentration is 2.9 mmol/l (<1.5).

Which of the following is an appropriate method of measuring adequate intravascular filling?

(Please select 1 option)

- LiDCO (lithium dilution cardiac output)
- Oesophageal Doppler monitoring
- PiCCO (pulse contour cardiac output) ← This is the correct answer
- Pulmonary artery flotation catheter (PAFC) ✕ Incorrect answer selected
- Transoesophageal echocardiography (TOE)

PiCCO gives indications of cardiac output, extravascular lung water, intravascular filling and only requires a central line and a PiCCO femoral arterial line and as such is relatively simple to use.

It would also not be unreasonable to insert an oesophageal Doppler device; however they have greater interobserver variation and require a degree of experience to use and are prone to misplacement.

LiDCO is still not validated or practical to be widely used.

PAFC are used widely in the USA however a study has questioned their safety and they have fallen out of favour in the UK.

TOE requires considerable expertise to use and is not suitable for cardiac output studies.

Work Smart Session - MRCP Part 1

Time taken: 35 mins 25 secs

Question: 22 of 47

A 56-year-old male with severe brain damage is apnoeic, unsedated, and temperature 36.9°C.

He is intubated and ventilated. His biochemistry is normal.

The combination of which of the following specialists would be able to confirm brain stem death?

(Please select 1 option)

- Consultant/Associate specialist with three years experience
- Consultant/Specialist registrar of two years experience
- Staff grade with five years experience/ Consultant ← This is the correct answer
- Senior house officer of two years experience/Specialist registrar of five years experience ✕ Incorrect answer selected
- Specialist registrar with five years experience/Specialist registrar with five years experience

Criteria for the confirmation of brain stem death have to be tested by a consultant and confirmed by a doctor of at least five years post- registration who has experience in the testing of brain stem death.

Work Smart Session - MRCP Part 1

Time taken: 35 mins 25 secs

Question: 23 of 47

A 67-year-old man is three days post-operation for a sigmoid colectomy. He has insulin dependent diabetes mellitus. He complains of dizziness and faintness.

His blood pressure is 80/50 mmHg, his pulse is 110 bpm, he has a respiratory rate 24/min, and he has SpO_2 99% on air. His blood glucose is 18 mmol/L (3.0-6.0 fasting).

His electrocardiogram shows ST depression of 2 mm in leads II, III and AVF.

Which of the following is the initial drug therapy for this patient?

(Please select 1 option)

- Aspirin 300mg
- Clexane 1 mg/kg subcutaneously
- Clopidogrel 75 mg
- Diamorphine 2.5 mg
- Glycerol tri-nitrate 800 mcg sublingually

His electrocardiogram shows ST depression of 2 mm in leads II, III and AVF.

Which of the following is the initial drug therapy for this patient?

(Please select 1 option)

○	Aspirin 300mg ← This is the correct answer
○	Clexane 1 mg/kg subcutaneously
○	Clopidogrel 75 mg
◉	Diamorphine 2.5 mg ✕ Incorrect answer selected
○	Glycerol tri-nitrate 800 mcg sublingually

Initial treatment of an acute coronary syndrome is aspirin 300 mg. This should be safe in the post-surgical patient with no signs of bleeding at three days post operation. Clexane would also be given, but aspirin initially.

The dose of clopidogrel is 300 mg in an acute coronary syndrome.

Diamorphine is used to treat anxiety and pain, neither of which is commented upon.

GTN would be reasonable to try, however the blood pressure is low.

Remember that in the diabetic chest pain may not be a feature of acute coronary syndrome due to autonomic dysfunction, and in most post-surgical patients myocardial infarct is silent.

Work Smart Session - MRCP Part 1

Time taken: 38 mins 14 secs

Question: 24 of 47

You are asked to see a 64-year-old man post oversew of a duodenal ulcer.

He is confused. His SpO_2 is 97 on oxygen. Pulse 110 beats per minute, blood pressure 100/50 mmHg, respiratory rate 32/min and his urine output is 10 ml in the last hour.

Which of the following is the most appropriate treatment for this man?

(Please select 1 option)

- 100% oxygen via face mask
- Central line and arterial line
- Colloid 500 ml stat
- Haloperidol 2.5 mg intravenously
- Noradrenaline via central line

○	100% oxygen via face mask
◉	Central line and arterial line ✕ Incorrect answer selected
○	Colloid 500 ml stat ← This is the correct answer
○	Haloperidol 2.5 mg intravenously
○	Noradrenaline via central line

Post-operative confusion is common in the elderly however this can be caused by a low perfusion state.

His observations are indicative of underfilling/dehydration.

Of the options given a fluid bolus is reasonable. Some would argue that 100% oxygen comes before fluids but with an SpO_2 of 97 it is unlikely that hypoxia is contributing to his problems (nonetheless oxygen therapy would be recommended).

The other options would come further down the line if initial interventions were unsuccessful and he deteriorated.

Work Smart Session - MRCP Part 1

Time taken: 41 mins 14 secs

Question: 25 of 47

A 74-year-old man with ischaemic heart disease is in the surgical High Dependency Unit following a Hartmann's procedure. He is in pain.

He has drained 100/200/300 mls of blood into his drains in the last 3 hours. His blood pressure is 110/80 mmHg, his pulse 105 beats/min, he has a respiratory rate 32/min, SpO2 100% on oxygen by face mask.

Haemoglobin	8.1 g/dL (13.0-18.0)
White cell count	4.5 $x10^9$/L (4-11 $x10^9$)
Platelets	132 $x10^9$/L (150-400 $x10^9$)

Which of the following is the next most appropriate therapeutic intervention?

(Please select 1 option)

- 2 units of packed red blood cells
- 1000 cmls of crystalloid stat
- Morphine 5 cmg intravenously
- Reassurance
- Return to theatre

White cell count	4.5 x10^9/L (4-11 x10^9)
Platelets	132 x10^9/L (150-400 x10^9)

Which of the following is the next most appropriate therapeutic intervention?

(Please select 1 option)

- (●) 2 units of packed red blood cells ✓ Correct
- ( ) 1000 cmls of crystalloid stat
- ( ) Morphine 5 cmg intravenously
- ( ) Reassurance
- ( ) Return to theatre

This is a difficult question as all the answers seem reasonable!

His observations could be caused by pain.

However in the face of a falling haemoglobin, a rising pulse rate and an increasing loss into his drains this patient needs to return to theatre.

His raised pulse rate and low haemoglobin suggest he needs resuscitation and they are not severe enough to warrant going straight to theatre without intervention. His blood pressure is not critically low and although many would give cyrstaolloid its not unreasonable in an elderly man with ischaemic heart disease to give blood if it is easily available.

Work Smart Session - MRCP Part 1

Time taken: 45 mins 12 secs

Question: 26 of 47

A 64-year-old man is admitted with central epigastric pain. Abdominal x ray shows a dilated bowel loop.

His temperature is 37.0°C, pulse 130 bpm, blood pressure 80/50 mmHg, respiratory rate 29/min, SpO_2 90% on air. His full blood count reveals:

Haemoglobin	13.0 g/dl	(13.0-18.0)
White cell count	3.2 x 10^9/l	(4-11)
Platelets	108 x 10^9/l	(150-400)
MCV	105 fl	(80-96)

Which of the following is the most likely diagnosis?

(Please select 1 option)

- Leaking aortic aneurysm
- MODS
- Pancreatitis
- Septic shock
- SIRS

Platelets	108 x 10^3/l	(150-400)
MCV	105 fl	(80-96)

Which of the following is the most likely diagnosis?

(Please select 1 option)

- ○ Leaking aortic aneurysm
- ○ MODS
- ◉ Pancreatitis ✕ Incorrect answer selected
- ○ Septic shock
- ○ SIRS ← This is the correct answer

We do not have an amylase available to confirm pancreatitis and the differential includes perforated ulcer. A leaking aortic aneurysm is still a possibility, however a decreased white cell count would not be expected. Similarly we do not have enough information to diagnose septic shock or MODS.

Systemic Inflammatory Response Syndrome (SIRS) is defined as:

1. Temperature >38°C or <36°C
2. Heart rate >90 beats/min
3. Respiratory rate >20 breaths/min or $PaCO_2$ <32 mmHg
4. WBC count >12,000/mm^3, <4000/mm^3, or >10% immature (bands) form.

Septic shock implies a confirmed focus of infection.

His full blood count reveals:

Haemoglobin	13.0 g/dl	(13.0-18.0)
White cell count	3.2 x 10^9/l	(4-11)
Platelets	108 x 10^9/l	(150-400)
MCV	105 fl	(80-96)

Which of the following is the most likely diagnosis?

(Please select 1 option)

- ○ Gall stone ileus
- ○ Ischaemic bowel
- ○ Pancreatitis ← This is the correct answer
- ◉ Perforated duodenal ulcer ✕ Incorrect answer selected
- ○ Small bowel obstruction

Ischaemic bowel and perforated duodenal ulcer would be high in the differential list.

However the history and raised mean corpuscular volume (MCV) suggests alcohol use and the severity of his observations would suggest a systemic inflammatory response which is more common with pancreatitis.

MCV	105 fl	(80-96)

Which of the following is the most appropriate treatment of this patient?

(Please select 1 option)

- ○ 100% oxygen ← This is the correct answer
- ○ 2 x 14 gauge venflons and 2 litres Hartmann's
- ◉ Intensive care ✕ Incorrect answer selected
- ○ Intubation and ventilation
- ○ Invasive monitoring

All of the above answers are reasonable, however resuscitation of the sick patient still follows the **A**irway, **B**reathing, **C**irculation algorithm.

Airway + 100% oxygen is the first part of that algorithm.

You are on call for hospital at night and are urgently called to a patient on the ward who is choking on a piece of steak visible in his oropharynx. He is in extremis with saturations of 87%.

Which of the following is the most appropriate immediate management for this patient?

(Please select 1 option)

○	Cricothyroidotomy
○	Finger sweep
◉	Heimlich manoeuvre ✓ Correct
○	High flow oxygen
○	Removal with forceps

A finger sweep is more likely to push the obstruction further into the airway and is no longer advocated.

High flow oxygen is the breathing part of A, B, C, and the airway is not clear.

Nasopharyngeal airways will not help in this situation.

Removal with forceps is potentially hazardous.

A Heimlich manoeuvre should be performed with the possibility of cricothyroidotomy in mind immediately thereafter if this procedure fails.

A 26-year-old female is admitted to ICU with severe asthma.

She is ventilated for one week, and receives IV co-amoxiclav/clarithromycin, magnesium, prednisolone, sedatives and muscle relaxants.

She improves gradually but two days after stopping muscle relaxants she still is unable to be weaned from ventilatory support.

On examination, she is alert but has flaccid weakness of all limbs.

Which of the following is the likely diagnosis?

(Please select 1 option)

○	Critical illness polyneuropathy
○	Guillain-Barré syndrome
◉	Hypermagnesaemia ✕ Incorrect answer selected
○	Prolonged neuromuscular blockade ← This is the correct answer
○	Steroid induced myopathy

The history suggests prolonged neuromuscular junction (NMJ) blockade which may be exacerbated by both corticosteroids and magnesium.

This condition was originally described with suxamethonium due to hereditary reductions in plasma cholinesterase activity. However, drugs and electrolyte abnormalities may exacerbate this.

Work Smart Session - MRCP Part 1

Time taken: 55 mins

Question: 30 of 47

A 62-year-old male with a history of ischaemic heart disease is admitted with chest pain of 13 hours' duration and some ST depression inferolaterally.

Which of the following would be the most appropriate treatment option for this patient?

(Please select 1 option)

- IV diamorphine 10 mg
- Oral aspirin 600 mg
- Oral isosorbide mononitrate 30 mg
- Oxygen 100%
- Subcutaneous low molecular weight heparin

A 62-year-old male with a history of ischaemic heart disease is admitted with chest pain of 13 hours' duration and some ST depression inferolaterally.

Which of the following would be the most appropriate treatment option for this patient?

(Please select 1 option)

○	IV diamorphine 10 mg
○	Oral aspirin 600 mg
○	Oral isosorbide mononitrate 30 mg
○	Oxygen 100%
◉	Subcutaneous low molecular weight heparin ✓ Correct

The treatment approach in this patient with acute coronary syndrome is

1. aspirin 300 mg
2. try some GTN.

If this fails then

- isosorbitdinitrate (ISDN) intravenously
- diamorphine (or morphine) 2.5 mg
- 4 L oxygen and
- subcutaneous low molecular weight heparin.

Work Smart Session - MRCP Part 1

Time taken: 59 mins 59 secs

Question: 31 of 47

A 24-year-old female is admitted with palpitations. Her pulse is 160 beats/min, blood pressure 70/50 mmHg and she has a respiratory rate 32/min.

She is awake, alert and oriented but dyspnoeic. Her electrocardiogram shows a regular rhythm with QRS complex width of 0.11s.

What is the most appropriate therapy for this patient?

(Please select 1 option)

- Adenosine 6 mg/6 mg/12 mg
- Amiodarone 300 mg
- Atenolol 50 mg
- Direct current cardioversion
- Verapamil 10 mg

Question: 31 of 47

A 24-year-old female is admitted with palpitations. Her pulse is 160 beats/min, blood pressure 70/50 mmHg and she has a respiratory rate 32/min.

She is awake, alert and oriented but dyspnoeic. Her electrocardiogram shows a regular rhythm with QRS complex width of 0.11s.

What is the most appropriate therapy for this patient?

(Please select 1 option)

○	Adenosine 6 mg/6 mg/12 mg
○	Amiodarone 300 mg
○	Atenolol 50 mg
◉	Direct current cardioversion ✓ Correct
○	Verapamil 10 mg

This is highly likely to be a narrow complex tachycardia.

Strictly speaking, as this patient is showing signs of haemodynamic decompromise (that is, systolic blood pressure less than 90) she should be immediately DC cardioverted under sedation/anaesthesia.

In practice, most people would try adenosine first whilst organising a cardioversion.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 2 mins 21 secs

Question: 32 of 47

A 67-year-old female is admitted with blackouts.

Her electrocardiogram shows ventricular escape with complete heart block. As you are standing there she blacks out once more. Her rhythm strip shows P wave asystole.

Which of the following would be the initial immediate treatment here after airway and breathing?

(Please select 1 option)

- Adenosine 6 mg
- Atropine 0.6 mg
- Percussion pacing
- Transcutaneous pacing
- Transvenous pacing

Submit answer | Skip question | Tag Question | Remove question

A 67-year-old female is admitted with blackouts.

Her electrocardiogram shows ventricular escape with complete heart block. As you are standing there she blacks out once more. Her rhythm strip shows P wave asystole.

Which of the following would be the initial immediate treatment here after airway and breathing?

(Please select 1 option)

○	Adenosine 6 mg
◉	Atropine 0.6 mg ✗ Incorrect answer selected
○	Percussion pacing ← This is the correct answer
○	Transcutaneous pacing
○	Transvenous pacing

Adenosine and atropine are not front line agents in this scenario, particularly adenosine which blocks atrioventricular (AV) conduction; minus one mark if you elected this.

Transvenous pacing is not a fast enough intervention here.

Transcutaneous pacing is the immediate management but percussion pacing may be effective as a holding measure whilst this is instituted.

(Percussion pacing involves gentle thumping of the lower left sternal edge with the fist.)

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 2 mins 34 secs

Question: 33 of 47

A 56-year-old man with septic shock is fully ventilated, on continuous veno-venous haemofiltration receiving noradrenaline, vancomycin and ciprofloxacin. He has a mean arterial pressure [MAP] of 60 mmHg which is then not improved after changing from noradrenaline to adrenaline. There is no evidence of myocardial dysfunction.

Which of the following would be the most appropriate next step in managing this patient?

(Please select 1 option)

- ACTH stimulation test
- Activated protein C
- Change of inotropes
- Hydrocortisone
- Nitric oxide

Submit answer | Skip question | Tag Question | Remove question

Questions Set : REF20435
Page Safety Tools

- Activated protein C
- Change of inotropes
- Hydrocortisone ✓ Correct
- Nitric oxide

Adrenaline is the first choice for change of inotropes if blood pressure is unresponsive to noradrenaline or dopamine.

The current 'Surviving Sepsis' guidelines do not recommend an adrenocorticotropic hormone (ACTH) stimulation test prior to administration of hydrocortisone. Hydrocortisone is preferable to dexamethasone. The addition of fludrocortisone to hydrocortisone is optional.

Activated protein C may be prescribed if there is sepsis-related organ dysfunction and a high risk of death (APACHE II 25 or more).

Changing inotropes again would probably not be effective.

Nitric oxide is a non-proven therapy in adult respiratory distress syndrome (ARDS).

This is a complicated area and difficult to remember if you are not regularly on ITU.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 14 mins 57 secs

Question: 34 of 47

A 56-year-old man diagnosed with systemic inflammatory response syndrome (SIRS) secondary to pancreatitis is admitted to the high dependency unit. He has a pulse of 109 beats/min and a blood pressure of 89/74 mmHg despite receiving IV fluids and urine output of 25 ml/hour after catheterisation.

Which of the following is the most appropriate course of action for this patient?

(Please select 1 option)

- A central line
- A CT abdomen
- A surgical referral
- An arterial line
- Broad spectrum antibiotics

Which of the following is the most appropriate course of action for this patient?

(Please select 1 option)

○	A central line ← This is the correct answer
○	A CT abdomen
○	A surgical referral
○	An arterial line
◉	Broad spectrum antibiotics ✕ Incorrect answer selected

Early goal directed therapy (EGDT) in cases of SIRS or septic shock is becoming increasingly recognised as potentially beneficial.

If fluids are not achieving haemodynamic stability and there is indication of hypoperfusion as indicated by oliguria or lactataemia then vigorous resuscitation is indicated.

EGDT aims to increase organ perfusion through

- Restoration of mean arterial pressure using inotropes if necessary
- Maintaining central venous pressure (CVP)
- Maintaining oxygenation, and
- Using $SjVO_2$ (jugular venous oxygen saturation) as a guide to oxygen utilisation at the tissue level.

$SjVO_2$ higher than 70% is indicative of organ hypoperfusion as oxygen is not being extracted.

Insertion of a central line above allows measurement of CVP, $SjVO_2$ and the use of inotropes.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 17 mins 16 secs

Question: 35 of 47

A 56-year-old man is admitted with epigastric pain after drinking heavily.

He has a temperature of 36.9°C, a pulse of 95/min, a blood pressure of 85/60 mmHg, and a respiratory rate of 32/min.

Investigations reveal:

Haemoglobin	12.6 g/dl	(13.0-18.0)
Platelets	169 x10^9/l	(150-400)
White cell count	3.9 x10^9/l	(4-11)

Which of the following is the diagnosis?

(Please select 1 option)

- Leaking aortic aneurysm
- Multi-organ dysfunction syndrome (MODS)
- Pancreatitis
- Septic shock
- Systemic inflammatory response syndrome (SIRS)

Which of the following is the diagnosis?

(Please select 1 option)

○	Leaking aortic aneurysm
○	Multi-organ dysfunction syndrome (MODS)
○	Pancreatitis
○	Septic shock
◉	Systemic inflammatory response syndrome (SIRS) ✓ Correct

We do not have an amylase available to confirm pancreatitis and the differential includes perforated ulcer.

A leaking aortic aneurysm is still a possibility, however a decreased white cell count would not be expected.

Similarly we do not have enough information to diagnose septic shock or MODS .

SIRS is defined as two or more of the following:

- Temperature more than 38°C or less than 36°C.
- Heart rate more than 90 beats/min.
- Respiratory rate more than 20 breaths/min or $PaCO_2$ less than 32 mmHg.
- WBC count 12,000/mm^3, less than 4000/mm^3 , or more than 10% immature (bands) form.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 19 mins 1 secs

Question: 36 of 47

A 34-year-old man with a known history of Crohn's disease was admitted to hospital with abdominal pain and features of perforation.

He underwent laparotomy and a perforation of the terminal ileum was found with free faecal fluid in the abdominal cavity. He was transferred to the intensive care unit (ITU).

Together with traditional antimicrobial and supportive ITU therapy, which of the following therapeutic measures is most likely to improve this patient's outcome?

(Please select 1 option)

- High-dose intravenous corticosteroids
- Low-dose intravenous corticosteroids
- Recombinant anti-endotoxin antibody
- Recombinant human antithrombin III
- Recombinant human tissue-factor pathway inhibitor

A 34-year-old man with a known history of Crohn's disease was admitted to hospital with abdominal pain and features of perforation.

He underwent laparotomy and a perforation of the terminal ileum was found with free faecal fluid in the abdominal cavity. He was transferred to the intensive care unit (ITU).

Together with traditional antimicrobial and supportive ITU therapy, which of the following therapeutic measures is most likely to improve this patient's outcome?

(Please select 1 option)

○	High-dose intravenous corticosteroids
○	Low-dose intravenous corticosteroids ← This is the correct answer
◉	Recombinant anti-endotoxin antibody ✕ Incorrect answer selected
○	Recombinant human antithrombin III
○	Recombinant human tissue-factor pathway inhibitor

The use of corticosteroids in sepsis remains controversial.

Meta-analyses of all the trials of high-dose steroids (for example, methylprednisolone 1 g) have confirmed that there is either no benefit, or even that there is an adverse effect in septic patients. However, more recent randomised controlled trials have suggested that there is a benefit in sepsis when lower physiological doses of steroids are given.

The precise mechanism is not fully understood, although it is well known that septic patients have low levels of endogenous steroids.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 22 mins 55 secs

Question: 37 of 47

An 82-year-old lady was admitted to hospital with fever and confusion.

On examination her temperature was 39°C, blood pressure was 80/45 mmHg with a pulse of 110 beats per minute regular with numerous petechiae over the abdomen.

After taking blood, it was noted that there was continued bleeding from the venous puncture site.

A urinary catheter was inserted and yielded 1500 ml of cloudy yellow offensive-smelling urine.

Which of the following is correct concerning this patient?

(Please select 1 option)

- Circulating levels of activated protein C (aPC) will be reduced
- Levels of D-dimer will be reduced
- Levels of fibrin degradation products (FDPs) will be reduced
- The activated partial thromboplastin time (APTT) will be below the normal range
- The platelet count is likely to be elevated

Tools

◉	Circulating levels of activated protein C (aPC) will be reduced ✓ Correct
○	Levels of D-dimer will be reduced
○	Levels of fibrin degradation products (FDPs) will be reduced
○	The activated partial thromboplastin time (APTT) will be below the normal range
○	The platelet count is likely to be elevated

The patient has disseminated intravascular coagulation (DIC) secondary to sepsis.

Given the history, the most likely source is the urinary tract.

Several coagulation abnormalities are seen in sepsis including:

APTT elevated
PT elevated
FDPs elevated
D-Dimers elevated

Platelets reduced
Fibrinogen reduced
Protein C reduced
Antithrombin reduced

◉	1 L normal saline intravenously as fast as possible. ✓ Correct
○	Commence intravenous low-dose dopamine
○	Give an 80 mg intravenous bolus of furosemide
○	Give 500 ml intravenous plasma expander over 4 hours
○	Urgent renal ultrasound

This question is dealing with postoperative acute renal failure. This what you might find on the morning ward round and wonder why the problem was not picked up during the night.

Note that even when the glomerular filtration rate is zero, the serum creatinine tends not to rise faster than 200 micro mol/l per day - so the patient's creatinine of 120 micro mol/l may be the beginning of established renal failure.

Immediate management consists of restoring the circulation as quickly as possible; debate still continues whether it is better to use colloid or crystalloid.

In this case it would seem to be more appropriate to use 1 L of normal saline as the time scale for plasma expander is too long.

If urine output and renal function recover as soon as intravascular volume is restored, the diagnosis of pre-renal uraemia is made; if they do not then the diagnosis is acute tubular necrosis (ATN).

In a seemingly previously cardiovascularly-well 30-year-old with hypotension, giving 1 L over a short time will not precipitate any problems.

There is little evidence to suggest that loop diuretics and dopamine are effective in the treatment of ATN.

The next problem is to find out why the patient was hypotensive after surgery.....

Question: 39 of 47

A 30-year-old woman becomes anuric 24 hours after a difficult laparoscopic cholecystectomy.

Investigations reveal:

Serum urea	9.2 mmol/l	(2.5-7.5)
Serum creatinine	120 micro mol/l	(60-110)

The blood pressure is 90/50 mmHg.

What is the next single most appropriate course of action in the management of the anuria?

(Please select 1 option)

- 1 L normal saline intravenously as fast as possible.
- Commence intravenous low-dose dopamine
- Give an 80 mg intravenous bolus of furosemide
- Give 500 ml intravenous plasma expander over 4 hours
- Urgent renal ultrasound

Question: 3 of 47

An 18-year-old with cerebral palsy is admitted after a respiratory arrest having been intubated by paramedics.

Nobody can gain intravenous access as the patient is too shut down. A femoral line is not possible due to contractures. You do not have the experience to perform central venous cannulation.

Which of the following is the best option for administering intravenous fluids/emergency drugs in this situation of inability to gain venous access?

(Please select 1 option)

○	Down the endotracheal tube
○	Intramuscular (IM)
◉	Intraosseous ✓ Correct
○	Nasogastric
○	Subcutaneous

Nasogastric, IM and subcutaneous are too slow and unreliable for emergency situations (although in cardiac arrest the endotracheal route is recognised).

Venous cut down is a possibility but requires skill in the procedure.

Intraosseous is still perfectly viable in the adult patient 2 cm below the tibial tuberosity on the antero-medial side or 2 cm proximal to the medial malleolus.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 31 mins 51 secs

Question: 40 of 47

A patient who is listed for excision of his operable squamous cell lung cancer, suffers a life-threatening haemoptysis on the ward.

Which of the following is the most appropriate treatment?

(Please select 1 option)

○	Antibiotics
○	Bronchial embolisation ← This is the correct answer
◉	Conservative care ✕ Incorrect answer selected
○	Radiotherapy
○	Tranexamic acid

Life-threatening haemoptysis is a medical emergency that requires prompt action.

Pulmonary angiography will identify the blood supply to the tumour and embolisation of this vessel(s) will immediately stem the bleeding.

The other options are also important in the long term management.

Antibiotics are used to prevent secondary bacterial infection.

Question: 41 of 47

A 15-year-old girl was admitted eight hours after taking an overdose of diazepam 30 mg and methotrexate 400 mg which her mother had been prescribed for rheumatoid arthritis.

On examination her Glasgow coma score (GCS) was 10.

Which one of the following is the most appropriate immediate action?

(Please select 1 option)

○	Assess respiratory function ← This is the correct answer
○	Perform immediate gastric lavage
○	Treat with activated charcoal
○	Treat with folinic acid
◉	Urgent liver function tests ✕ Incorrect answer selected

Her depressed GCS is due to the diazepam and the most appropriate inital treatment would be to assess her respiratory function prior to giving her folinic acid.

Methotrexate overdose is extremely rare but potentially fatal with hepatotoxicity and renal toxicity reported.

The most appropriate treatment is folinic acid (leucovorin).

It is too late to consider gastric lavage or activated charcoal.

Question: 42 of 47

An 18-year-old woman sustains severe head injuries in a road traffic accident.

The following day her investigations show:

Sodium	160 mmol/l	(137-144)
Potassium	3.7 mmol/l	(3.5-4.9)
Chloride	120 mmol/l	(95-107)
Urea	3.0 mmol/l	(2.5-7.5)
Creatinine	90 µmol/l	(60- 110)

Which one of the following statements is correct?

(Please select 1 option)

- Rapid rehydration with 5% dextrose is indicated
- She has the syndrome of inappropriate antidiuretic hormone secretion (SIADH)
- She should be treated with sodium restriction
- She will have a hypercholraemic acidosis
- Urine osmolality will be low

Urea	3.0 mmol/l	(2.5-7.5)
Creatinine	90 µmol/l	(60- 110)

Which one of the following statements is correct?

(Please select 1 option)

- ○ Rapid rehydration with 5% dextrose is indicated
- ○ She has the syndrome of inappropriate antidiuretic hormone secretion (SIADH)
- ◉ She should be treated with sodium restriction ✕ Incorrect answer selected
- ○ She will have a hypercholraemic acidosis
- ○ Urine osmolality will be low ← This is the correct answer

There is a marked hypernatraemia with elevated chloride but normal potassium and urea in a patient with severe head injuries.

The likely cause of this presentation is diabetes insipidus. Urine osmolality is therefore likely to be low.

You cannot say that she has a hyperchloraemic acidosis as you do not have her bicarbonate concentration but if you assume that the anion gap would be normal, that is 10-12, then this would suggest that the bicarbonate is elevated, suggesting either a metabolic alkalosis or respiratory acidosis with compensation.

Although restoration of normal volaemia and osmolality is required, giving 5% dextrose may exacerbate any cerebral oedema and so correction should be gradual.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 36 mins 25 secs

Question: 43 of 47

The pulmonary vascular system is different from the systemic circulation in that the pulmonary system demonstrates which of the following?

(Please select 1 option)

- High pressures, high flow rates, highly compliant vessels
- High pressures, high flow rates, low compliance vessels
- Low pressures, high flow rates, high compliance vessels
- Low pressures, low flow rates, high compliance vessels
- Low pressures, low flow rates, low compliance vessels

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 39 mins 12 secs

Question: 43 of 47

The pulmonary vascular system is different from the systemic circulation in that the pulmonary system demonstrates which of the following?

(Please select 1 option)

- High pressures, high flow rates, highly compliant vessels
- High pressures, high flow rates, low compliance vessels
- Low pressures, high flow rates, high compliance vessels
- **Low pressures, low flow rates, high compliance vessels** ✓ Correct
- Low pressures, low flow rates, low compliance vessels

The normal pulmonary circulation is characterised by low pressures, low flow rates, high compliance vessels.

Questions Set : REF4440
Page
Safety
Tools

A 43-year-old solicitor had an onset of severe, crushing, substernal chest pain while attending a football match. He collapsed on his way to the car.

Bystander cardiorespiratory resuscitation was begun immediately and continued until arrival in the casualty department where an endotracheal tube was inserted and ventilation was maintained on 100% oxygen.

Blood gas analysis revealed:

pH	7.13	(7.35-7.45)
P_aO_2	560 mmHg	(90-110)
P_aCO_2	18 mmHg	(35-45)
Bicarbonate	5.8 mmol/l	(20-30)
S_aO_2	98%	(>90)

Based on these laboratory values, which of the following statements best describes his current pathophysiology?

(Please select 1 option)

- He is demonstrating a primary respiratory alkalosis
- He probably developed a large right to left intracardiac shunt
- His anion gap is probably normal
- His oxyhaemoglobin curve is shifted to the left
- His pulmonary artery pressure is probably elevated

P_aO_2	560 mmHg	(90-110)
P_aCO_2	18 mmHg	(35-45)
Bicarbonate	5.8 mmol/l	(20-30)
S_aO_2	98%	(>90)

Based on these laboratory values, which of the following statements best describes his current pathophysiology?

(Please select 1 option)

- He is demonstrating a primary respiratory alkalosis
- He probably developed a large right to left intracardiac shunt ✕ Incorrect answer selected
- His anion gap is probably normal
- His oxyhaemoglobin curve is shifted to the left
- His pulmonary artery pressure is probably elevated ← This is the correct answer

This relatively young patient with severe central chest pain has probably arrested due to myocardial infarction and arrhythmia.

His gases reveal high PO_2 following 100% O_2 but severe acidosis due to the arrest and lactic acidosis thus the anion gap would be high.

He does not have a primary ventilatory failure as his PO_2 is high.

There is no left to right shunting and high pulmonary pressures would be expected after this arrest scenario.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 44 mins 42 secs

Question: 45 of 47

Which of the following is not a feature of cannabinoids?

(Please select 1 option)

- (●) Bioavailability after oral administration is about 70%
- ( ) Inhibits eicosanoid synthesis
- ( ) Lowers intraocular pressure
- ( ) Naloxone blocks the antinociceptive actions of cannabinoids
- ( ) 9-tetrahydrocannabinol is the active constituent of the resin

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 45 mins 43 secs

Question: 45 of 47

Which of the following is not a feature of cannabinoids?

(Please select 1 option)

- (●) Bioavailability after oral administration is about 70% ✓ Correct
- ( ) Inhibits eicosanoid synthesis
- ( ) Lowers intraocular pressure
- ( ) Naloxone blocks the antinociceptive actions of cannabinoids
- ( ) 9-tetrahydrocannabinol is the active constituent of the resin

Cannabinoids are derived from the resin of cannabis sativa, and 9-tetrahydrocannabinol (9-THC) is its most important pharmacologically active constituent.

Oral bioavailability of THC whether given in the pure form or as THC in marijuana is low and extremely variable ranging between five and 20% with effects occurring 0.5-3 hours later. Bioavailability of THC in a marijuana cigarette or pipe also rarely exceeds 10 to 20%.

Naloxone and other opioid receptor antagonists block the analgesic actions of cannabinoids.

Synthetic cannabinoids reduce arachidonic acid-induced inflammation by inhibiting eicosanoid production.

Question: 46 of 47

Which of the following does not have a role in the management of chronic cancer pain?

(Please select 1 option)

○	Carbamazepine
○	Clodronate
○	Dexamethasone
○	Nifedipine
◉	Pinavarium ✓ Correct

Pinavarium is used to reduce the pain duration in irritable bowel syndrome (IBS).

Carbamazepine is in use for the treatment of neuropathic pain of malignancy, diabetes and other disorders.

Clodronate inhibits osteoclastic bone resorption and is used to treat malignant bone pain and the associated hypercalcaemia.

The corticosteroids are used to treat pain from central nervous system tumours.

Reducing the inflammation and oedema relieves the pain caused by neural compression.

Nifedipine helps relieve painful oesophageal spasm and tenesmus associated with gastrointestinal tumours.

Painful bladder spasm may be relieved by oxybutinin.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 47 mins 13 secs

Question: 47 of 47

On discovering an unconscious patient in a pre-hospital environment basic life support needs to be considered.

Which of the following statements is correct?

(Please select 1 option)

- Cross infection with hepatitis B may occur during CPR
- On confirming an arrest, a ratio of 30 compressions to 2 ventilations should be adopted at all times
- On confirming an arrest, one minute of CPR should be performed before leaving the patient and getting help
- Rapid assessment of the airway and breathing is our primary objective
- Two effective rescue breaths should be given once apnoea is confirmed

Cross infection with hepatitis B may occur during CPR

- (●) On confirming an arrest, a ratio of 30 compressions to 2 ventilations should be adopted at all times ✓ Correct
- ( ) On confirming an arrest, one minute of CPR should be performed before leaving the patient and getting help
- ( ) Rapid assessment of the airway and breathing is our primary objective
- ( ) Two effective rescue breaths should be given once apnoea is confirmed

Assessing the environment to see if it is safe to approach is the first priority when considering providing aid to an unconscious patient. You do not want to become a casualty yourself.

Cardiopulmonary resuscitation (CPR) related infections are extremely rare, although tuberculosis, human immunodeficiency virus (HIV) and *Neisseria meningitidis* have all been recorded.

Most of the 15 cases were due to bacterial agents and the three HIV infections were from major cutaneous wound contamination.

No case reports of hepatitis B have been recorded (Ann Int Med 1998;129(10):813-828).

Once it has been confirmed that the patient is not breathing you must get help or alert the emergency services, even if this means leaving the patient (this is especially important in a pre-hospital environment).

However, if the patient is an infant or child, a victim of trauma, a near drowning or if drug or alcohol intoxication is likely, then one minute of CPR should be performed before going for help.

The new ALS guidelines (pdf) correct ratio of compressions to ventilations is 30:2 regardless of the number of rescuers present.

Work Smart Session - MRCP Part 1

Time taken: 8 mins 2 secs

Question: 4 of 47

A 19-year-old man is admitted with palpitations.

His pulse is 160 beats/min, blood pressure 80/50 mmHg, and he has a respiratory rate of 34/min. His electrocardiogram shows a regular QRS with a width of 0.14 seconds and a delta wave is seen.

Which of the following, used intravenously, is the most appropriate treatment for this man?

(Please select 1 option)

○	Adenosine 6 mg
◉	Amiodarone 300 mg ✓ Correct
○	Digoxin 500 mcg
○	Diltiazem 15 mg
○	Verapamil 10 mg

This young man has a prolonged QRS and the delta wave which signifies Wolff-Parkinson-White (WPW) syndrome.

Although adenosine is used in patients in whom WPW is not suspected, one uses this with caution in WPW as suggested in this article from eMedicine.

All the other medications are contraindicated in WPW as they may worsen the arrhythmia.

Work Smart Session - MRCP Part 1

Time taken: 8 mins 59 secs

Question: 5 of 47

A patient needs central venous access for total parenteral nutrition (TPN).

Which of the following is the cleanest site for placement?

(Please select 1 option)

- Left femoral
- Left internal jugular
- Right femoral
- Right internal jugular
- Right subclavian ✓ Correct

Right or left subclavian is regarded as the cleanest site for central venous access. It also the most tolerated by patients.

However the incidence of subclinical pneumothorax even in the hands of experienced clinicians has led to it falling out of favour.

Work Smart Session - MRCP Part 1

Time taken: 8 mins 59 secs

Question: 6 of 47

A 67-year-old man complains of dizziness and faintness. He has insulin dependent diabetes mellitus and he had a sigmoid colectomy three days previously.

His blood pressure is 80/50 mmHg, his pulse 110 beats per min, his respiratory rate 24/min, and he has SpO_2 99% on air. His plasma glucose concentration is 18 mmol/l (3.0-6.0 fasting).

Which of the following is the most appropriate investigation for this patient?

(Please select 1 option)

- Arterial blood gas
- Chest x ray
- Electrocardiogram
- Serum lactate
- Urine ketones

previously.

His blood pressure is 80/50 mmHg, his pulse 110 beats per min, his respiratory rate 24/min, and he has SpO_2 99% on air. His plasma glucose concentration is 18 mmol/l (3.0-6.0 fasting).

Which of the following is the most appropriate investigation for this patient?

(Please select 1 option)

◉	Arterial blood gas ✕ Incorrect answer selected
○	Chest x ray
○	Electrocardiogram ← This is the correct answer
○	Serum lactate
○	Urine ketones

This man may have a cardiac cause for his dizziness. The highest prevalence of myocardial infarction (MI) is 72 hours post- operation. Patients with diabetes may not have chest pain due to autonomic dysfunction.

The differential diagnosis would include pulmonary embolus. It may also include diabetic ketoacidosis, but this would be unlikely with his glucose at 18 mmol/L and would not directly explain his hypotension. Also, he would be expected to have a slightly higher respiratory rate than 24/min.

The most appropriate immediate investigation in this scenario would be ECG.

A 23-year-old man with known peanut allergy presented to the Emergency Department with anaphylaxis. He has a swollen face and lips. His BP is 90/60 mmHg, pulse 110 bpm and he is wheezy.

Which of the following formulations of adrenaline should be given?

(Please select 1 option)

- 0.5 ml of 1:10000 adrenaline IM
- **0.5 ml of 1:1000 adrenaline IM** ✓ Correct
- 5 ml of 1:1000 adrenaline IM
- 10 ml of 1:10000 adrenaline IV
- Nebulised adrenaline

"For adults, a dose of 0.5 mL adrenaline 1:1000 solution (500 micrograms) should be administered intramuscularly, and repeated after about five minutes in the absence of clinical improvement or if deterioration occurs after the initial treatment especially if consciousness becomes - or remains - impaired as a result of hypotension. In some cases several doses may be needed, particularly if improvement is transient."
Resuscitation Council UK.

Adult EpiPen which allergy sufferers can carry with them contains 0.3 mg adrenaline in a 1:1000 dilution for intramuscular (IM) injection.

Which of the following statements regarding the internal jugular vein and relations is true?

(Please select 1 option)

- Lies medial to the common carotid artery
- On the right side crosses the first part of the subclavian artery ← This is the correct answer
- Originates at the sphenoid sinus
- Passes posterior to the internal carotid artery ✕ Incorrect answer selected
- The right internal jugular is usually smaller than the left

The anatomy of the jugular vein is important given that it is the site of insertion of central venous catheters.

The internal jugular vein originates at the jugular foramen.

It initially lies posterior and lateral to the carotid artery.

As it descends in the carotid sheath it lies lateral first to the internal then the common carotid artery within the carotid sheath.

It passes anterior to the subclavian artery to join the subclavian vein to form the inonimate vein.

The internal jugular vein receives a lymphatic trunk at its union with the subclavian vein.

The internal jugular vein is usually of considerable size, and the right internal jugular is usually larger than the left.

The external jugular vein drains into the subclavian vein.

Question: 9 of 47

Which of the following statements regarding the internal jugular vein and relations is true?

(Please select 1 option)

- (●) Lies lateral to the common carotid artery ✓ Correct
- ( ) Originates at the carotid canal
- ( ) Passes behind the clavicle to join the superior vena cava
- ( ) Passes posterior to the subclavian artery
- ( ) Receives a lymphatic trunk at its union with the external jugular vein.

The internal jugular vein originates at the jugular foramen.

It initially lies posterior to the carotid artery as it descends in the carotid sheath it lies lateral first to the internal then the common carotid artery within the carotid sheath.

It passes anterior to the subclavian artery to join the subclavian vein and then form the brachiocephalic vein; the left and right brachiocephalic veins unite to form the superior vena cava.

The internal jugular vein receives a lymphatic trunk at its union with the subclavian vein.

The external jugular vein drains into the subclavian vein.

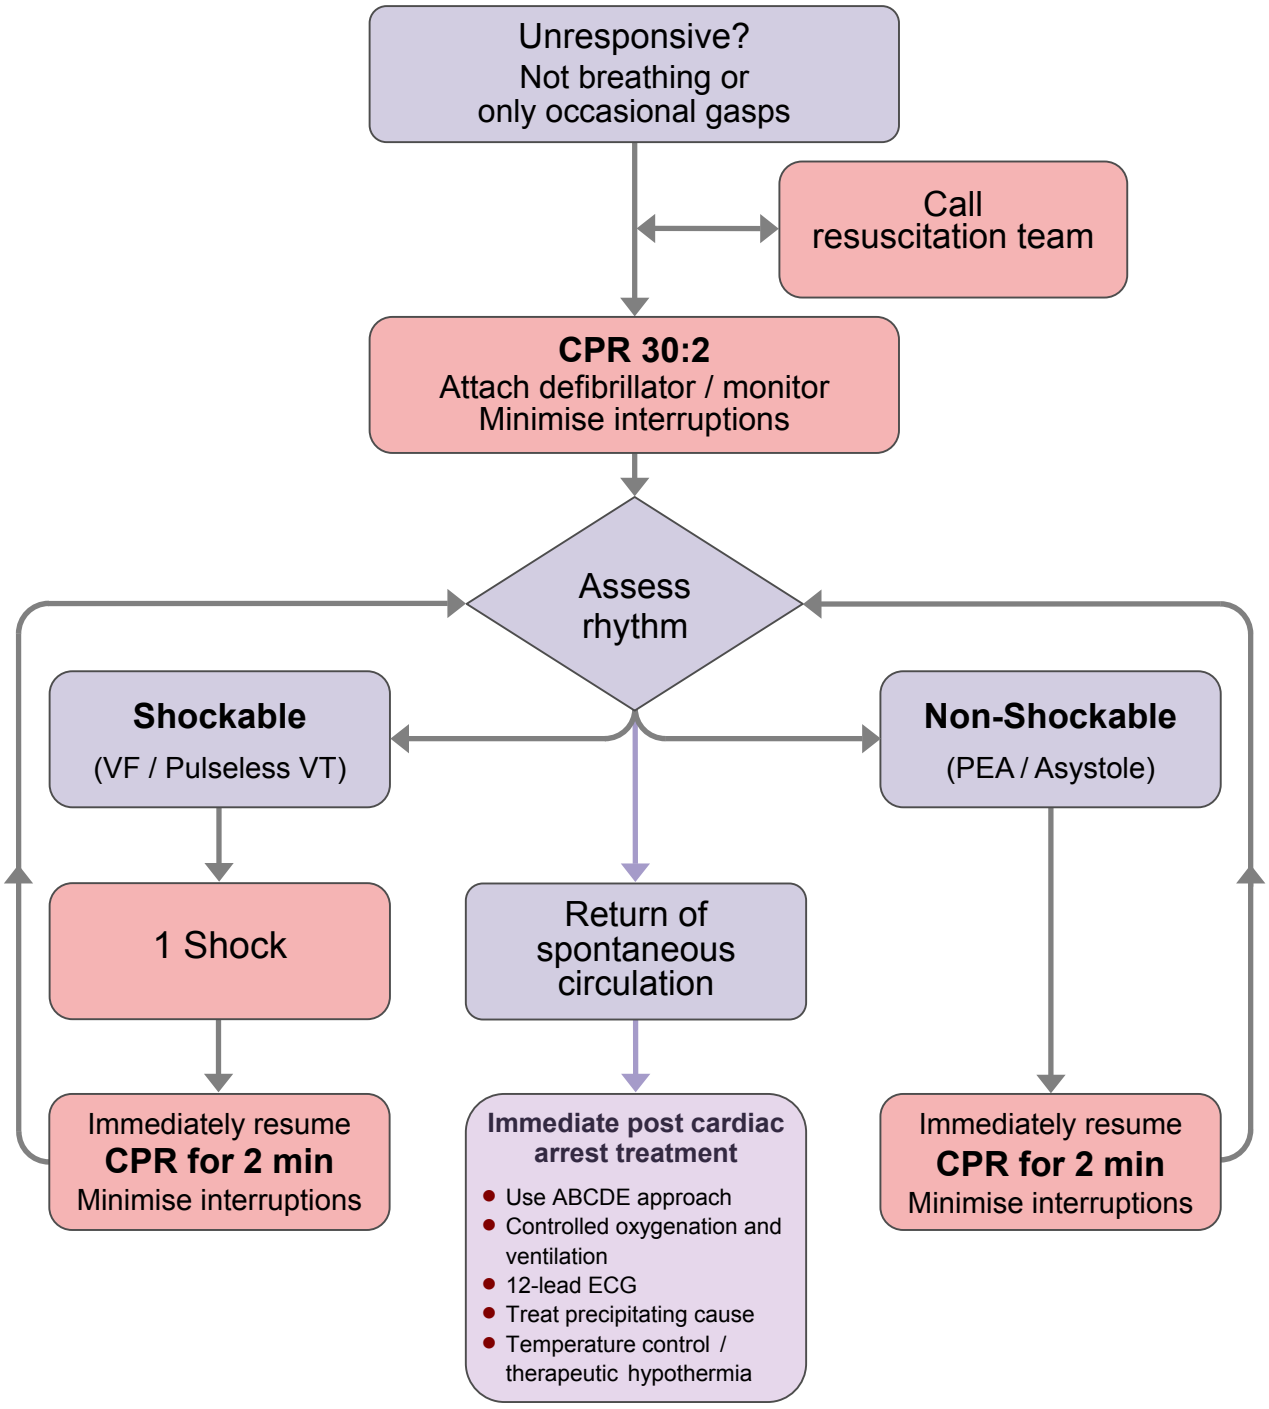
2010 Resuscitation Guidelines

Resuscitation Council (UK)

Adult Advanced Life Support



During CPR

- Ensure high-quality CPR: rate, depth, recoil
- Plan actions before interrupting CPR
- Give oxygen
- Consider advanced airway and capnography
- Continuous chest compressions when advanced airway in place
- Vascular access (intravenous, intraosseous)
- Give adrenaline every 3-5 min
- Correct reversible causes

Reversible Causes

- Hypoxia
- Hypovolaemia
- Hypo- / hyperkalaemia / metabolic
- Hypothermia
- Thrombosis - coronary or pulmonary
- Tamponade - cardiac
- Toxins
- Tension pneumothorax

2 Adult Basic Life Support

Introduction

This chapter contains the guidelines for out-of-hospital, single rescuer, adult basic life support (BLS). Like the other guidelines in this publication, it is based on the document *2010 International Consensus on Cardiopulmonary Resuscitation and Emergency Cardiovascular Care Science with Treatment Recommendations* (CoSTR), which was published in October 2010. Basic life support refers to maintaining airway patency and supporting breathing and the circulation without the use of equipment other than a protective device.

It is important that those who may be present at the scene of a cardiac arrest, particularly lay bystanders, should have learnt the appropriate resuscitation skills and be able to put them into practice. Simplification of the BLS sequence continues to be a feature of these guidelines, but, in addition, there is now advice on who should be taught what skills, particularly chest-compression-only or chest compression and ventilation. Within this advice, allowance has been made for the rescuer who is unable or unwilling to perform rescue breathing, and for those who are untrained and receive telephone advice from the ambulance service.

Guidelines 2000 introduced the concept of checking for 'signs of a circulation'. This change was made because of the evidence that relying on a check of the carotid pulse to diagnose cardiac arrest is unreliable and time-consuming, mainly, but not exclusively, when attempted by non-healthcare professionals.[9] Subsequent studies have shown that checking for breathing is also prone to error, particularly as agonal gasps are often misdiagnosed as normal breathing.[10] In Guidelines 2010 the absence of normal breathing continues to be the main sign of cardiac arrest in a non-responsive victim. Once cardiopulmonary resuscitation (CPR) has started, it is now recommended that the rescuer should only stop CPR if the victim shows signs of regaining consciousness, such as coughing, opening his eyes, speaking, or moving purposefully, as well as breathing normally.

Guideline changes

It is well documented that interruptions in chest compression are common[11, 12] and are associated with a reduced chance of survival.[13] The 'perfect' solution is to deliver continuous compressions whilst giving ventilations independently. This is possible when the victim has an advanced airway in place, and is discussed in the adult advanced life support (ALS) chapter. Compression-only CPR is another way to increase the number of compressions given and will, by definition, eliminate pauses. It is effective for a

limited period only (probably less than 5 min)[14] and is not recommended as the standard management of out-of-hospital cardiac arrest.

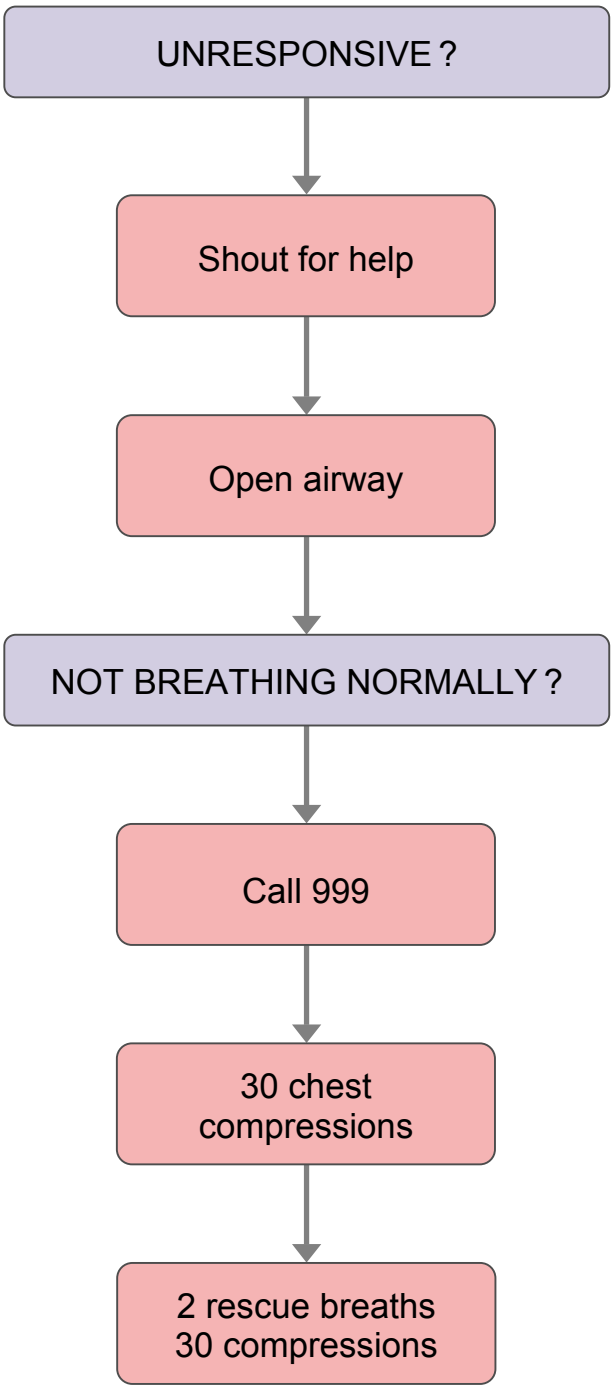
It is also known that chest compressions, both in hospital and outside, are often undertaken with insufficient depth and at the wrong rate.[12, 15]

The following changes in the BLS guidelines have been made to reflect the importance placed on chest compression, particularly good quality compressions, and to attempt to reduce the number and duration of pauses in chest compression:

1. When obtaining help, ask for an automated external defibrillator (AED), if one is available.
2. Compress the chest to a depth of 5-6 cm and at a rate of 100-120 min^{-1}.
3. Give each rescue breath over 1 s rather than 2 s.
4. Do not stop to check the victim or discontinue CPR unless the victim starts to show signs of regaining consciousness, such as coughing, opening his eyes, speaking, or moving purposefully AND starts to breathe normally.
5. Teach CPR to laypeople with an emphasis on chest compression, but include ventilation as the standard, particularly for those with a duty of care.

In addition, advice has been added on the use of oxygen, and how to manage a victim who regurgitates stomach contents during resuscitation.

Adult basic life support algorithm



Adult basic life support sequence

Basic life support consists of the following sequence of actions:

1. Make sure the victim, any bystanders, and you are safe.

2. Check the victim for a response.

- Gently shake his shoulders and ask loudly, 'Are you all right?'

3A. If he responds:

- Leave him in the position in which you find him provided there is no further danger.
- Try to find out what is wrong with him and get help if needed.
- Reassess him regularly.

3B. If he does <u>not</u> respond:

- Shout for help.
- Turn the victim onto his back and then open the airway using head tilt and chin lift:
    - Place your hand on his forehead and gently tilt his head back.
    - With your fingertips under the point of the victim's chin, lift the chin to open the airway.

4. Keeping the airway open, look, listen, and feel for normal breathing.

- Look for chest movement.
- Listen at the victim's mouth for breath sounds.
- Feel for air on your cheek.

In the first few minutes after cardiac arrest, a victim may be barely breathing, or taking infrequent, noisy, gasps. This is often termed agonal breathing and must not be confused with normal breathing.

Look, listen, and feel for **<u>no more</u>** than **10 s** to determine if the victim is breathing normally. If you have any doubt whether breathing is normal, act as if it is **<u>not</u>** normal.

5A. If he <u>is</u> breathing normally:

- Turn him into the recovery position (**see below**).
- Summon help from the ambulance service by mobile phone. If this is not possible, send a bystander. Leave the victim only if no other way of obtaining help is possible.
- Continue to assess that breathing remains normal. If there is any doubt about the presence of normal breathing, start CPR (5B).

5B. If he is <u>not</u> breathing normally:

- Ask someone to call for an ambulance and bring an AED if available. If you are on your own, use your mobile phone to call for an ambulance. Leave the victim only when no other option exists for getting help.
- Start chest compression as follows:
    - Kneel by the side of the victim.
    - Place the heel of one hand in the centre of the victim's chest (which is the lower half of the victim's sternum (breastbone)).
    - Place the heel of your other hand on top of the first hand.
    - Interlock the fingers of your hands and ensure that pressure is not applied over the victim's ribs. Do not apply any pressure over the upper abdomen or the bottom end of the sternum.
    - Position yourself vertically above the victim's chest and, with your arms straight, press down on the sternum 5 - 6 cm.
    - After each compression, release all the pressure on the chest without losing contact between your hands and the sternum. Repeat at a rate of 100 - 120 min^{-1}.
    - Compression and release should take an equal amount of time.

6A. Combine chest compression with rescue breaths:

- After 30 compressions open the airway again using head tilt and chin lift.
- Pinch the soft part of the victim's nose closed, using the index finger and thumb of your hand on his forehead.
- Allow his mouth to open, but maintain chin lift.
- Take a normal breath and place your lips around his mouth, making sure that you have a good seal.
- Blow steadily into his mouth whilst watching for his chest to rise; take about one second to make his chest rise as in normal breathing; this is an effective rescue breath.
- Maintaining head tilt and chin lift, take your mouth away from the victim and watch for his chest to fall as air comes out.
- Take another normal breath and blow into the victim's mouth once more to give a total of two effective rescue breaths. The two breaths should not take more than 5 s. Then return your hands without delay to the correct position on the sternum and give a further 30 chest compressions.
- Continue with chest compressions and rescue breaths in a ratio of 30:2.
- Stop to recheck the victim only if he starts to show signs of regaining consciousness, such as coughing, opening his eyes, speaking, or moving purposefully AND starts to breathe normally; otherwise **do not interrupt resuscitation.**

If the initial rescue breath of each sequence does not make the chest rise as in normal breathing, then, before your next attempt:

- Check the victim's mouth and remove any visible obstruction.
- Recheck that there is adequate head tilt and chin lift.
- Do not attempt more than two breaths each time before returning to chest compressions.

If there is more than one rescuer present, another should take over CPR about every 1-2 min to prevent fatigue. Ensure the minimum of delay during the changeover of rescuers, and do not interrupt chest compressions.

6B. Compression-only CPR

- If you are not trained to, or are unwilling to give rescue breaths, give chest compressions only.
- If chest compressions only are given, these should be continuous at a rate of 100 - 120 min^{-1}.
- Stop to recheck the victim only if he starts to show signs of regaining consciousness, such as coughing, opening his eyes, speaking, or moving purposefully AND starts to breathe normally; otherwise **do not interrupt resuscitation.**

7. Continue resuscitation until:

- qualified help arrives and takes over,
- the victim starts to show signs of regaining consciousness, such as coughing, opening his eyes, speaking, or moving purposefully AND starts to breathe normally, OR
- you become exhausted.

Further points related to basic life support

Risks to the rescuer and victim

The safety of both the rescuer and victim are paramount during a resuscitation attempt. There have been few incidents of rescuers suffering adverse effects from undertaking CPR, with only isolated reports of infections such as tuberculosis (TB) and severe acute respiratory distress syndrome (SARS). Transmission of HIV during CPR has never been reported.[16]

There have been no human studies to address the effectiveness of barrier devices during CPR; however, laboratory studies have shown that certain filters, or barrier devices with one-way valves, prevent transmission of oral bacteria from the victim to the rescuer during mouth-to-mouth ventilation. Rescuers should take appropriate safety precautions where feasible, especially if the victim is known to have a serious infection

such as TB or SARS. During an outbreak of a highly infectious condition (such as SARS), full protective precautions for the rescuer are essential.

Initial rescue breaths

During the first few minutes after non-asphyxial cardiac arrest the blood oxygen content remains high. Therefore, ventilation is less important than chest compression at this time.

It is well recognised that skill acquisition and retention are aided by simplification of the BLS sequence of actions. It is also recognised that rescuers are frequently unwilling to carry out mouth-to-mouth ventilation for a variety of reasons, including fear of infection and distaste for the procedure. For these reasons, and to emphasise the priority of chest compressions, it is recommended that, in adults, CPR should start with chest compressions rather than initial ventilations.

Jaw thrust

The jaw thrust technique is not recommended for lay rescuers because it is difficult to learn and perform. Therefore, the lay rescuer should open the airway using a head-tilt-chin-lift manoeuvre for both injured and non-injured victims.

Agonal gasps

Agonal gasps are present in up to 40% of cardiac arrest victims.[10] Therefore laypeople should be taught to begin CPR if the victim is unconscious (unresponsive) and not breathing normally. It should be emphasised during training that agonal gasps occur commonly in the first few minutes after sudden cardiac arrest; they are an indication for starting CPR immediately and should not be confused with normal breathing.

Use of oxygen during basic life support

There is no evidence that oxygen administration is of benefit during basic life support in the majority of cases of cardiac arrest before healthcare professionals are available with equipment to secure the airway. Its use may lead to interruption in chest compressions, and is not recommended, except in cases of drowning (see below).

Mouth-to-nose ventilation

Mouth-to-nose ventilation is an effective alternative to mouth-to-mouth ventilation. It may be considered if the victim's mouth is seriously injured or cannot be opened, if the rescuer is assisting a victim in the water, or if a mouth-to-mouth seal is difficult to achieve.

Mouth-to-tracheostomy ventilation

Mouth-to-tracheostomy ventilation may be used for a victim with a tracheostomy tube or tracheal stoma who requires rescue breathing.

Bag-mask ventilation

Considerable practice and skill are required to use a bag and mask for ventilation. The lone rescuer has to be able to open the airway with a jaw thrust whilst simultaneously holding the mask to the victim's face. It is a technique that is appropriate only for lay rescuers who work in highly specialised areas, such as where there is a risk of cyanide poisoning or exposure to other toxic agents. There are other specific circumstances in which non-healthcare providers receive extended training in first aid, which could include training, and retraining, in the use of bag-mask ventilation. The same strict training that applies to healthcare professionals should be followed and the two-person technique is preferable.

Chest compression

In most circumstances it will be possible to identify the correct hand position for chest compression without removing the victim's clothes. If in any doubt, remove outer clothing.

Each time compressions are resumed on an adult, the rescuer should place his hands on the lower half of the sternum. It is recommended that this location be taught in a simple way, such as 'place the heel of your hand in the centre of the chest with the other hand on top.' This teaching should be accompanied by a demonstration of placing the hands on the lower half of the sternum.[17] Use of the internipple line as a landmark for hand placement is not reliable.

Performing chest compression:

a. Compress the chest at a rate of 100-120 min^{-1}.
b. Each time compressions are resumed, place your hands without delay 'in the centre of the chest' (see above).
c. Pay attention to achieving the full compression depth of 5-6 cm (for an adult).
d. Allow the chest to recoil completely after each compression.
e. Take approximately the same amount of time for compression and relaxation.
f. Minimise interruptions in chest compression.
g. Do not rely on a palpable carotid or femoral pulse as a gauge of effective arterial flow.
h. 'Compression rate' refers to the speed at which compressions are given, not the total number delivered in each minute. The number delivered is

determined not only by the rate, but also by the number of interruptions to open the airway, deliver rescue breaths, and allow AED analysis.

Compression-only CPR

Studies have shown that compression-only CPR may be as effective as combined ventilation and compression in the first few minutes after non-asphyxial arrest. However, chest compression combined with rescue breaths is the method of choice for CPR by trained lay rescuers and professionals and should be the basis for lay-rescuer education. Lay rescuers who are unable or unwilling to provide rescue breaths, should be encouraged to give chest compressions alone. When advising untrained laypeople by telephone, ambulance dispatchers should give instruction on compression-only CPR.[18, 19, 19a]

Regurgitation during CPR

Regurgitation of stomach contents is common during CPR, particularly in victims of drowning. If regurgitation occurs:

- Turn the victim away from you.
- Keep him on his side and prevent him from toppling on to his front.
- Ensure that his head is turned towards the floor and his mouth is open and at the lowest point, thus allowing vomit to drain away.
- Clear any residual debris from his mouth with your fingers; and immediately turn him on to his back, re-establish an airway, and continue rescue breathing and chest compressions at the recommended rate.

Teaching CPR

Compression-only CPR has potential advantages over chest compression and ventilation, particularly when the rescuer is an untrained or partially-trained layperson. However, there are situations where combining chest compressions with ventilation is better, for example in children, asphyxial arrests, and prolonged arrests.[20, 21] Therefore, CPR should remain standard care for healthcare professionals and the preferred target for laypeople, the emphasis always being on minimal interruption in compressions.

A simple, education-based approach is recommended:

- Ideally, full CPR skills should be taught to all citizens.
- Initial or limited-time training should always include chest compression.
- Subsequent training (which may follow immediately or at a later date) should include ventilation as well as chest compression.

CPR training for citizens should be promoted, but untrained lay people should be encouraged to give chest compressions only, when possible and appropriate with telephone advice from an ambulance dispatcher.

Those laypeople with a duty of care, such as first aid workers, lifeguards, and child minders, should be taught chest compression and ventilation.

Over-the-head CPR

Over-the-head CPR for a single rescuer and straddle CPR for two rescuers may be considered for resuscitation in confined spaces.

Recovery position

There are several variations of the recovery position, each with its own advantages. No single position is perfect for all victims. The position should be stable, near a true lateral position with the head dependent, and with no pressure on the chest to impair breathing.

The RC(UK) recommends the following sequence of actions to place a victim in the recovery position:

- Remove the victim's glasses, if present.
- Kneel beside the victim and make sure that both his legs are straight.
- Place the arm nearest to you out at right angles to his body, elbow bent with the hand palm-up.
- Bring the far arm across the chest, and hold the back of the hand against the victim's cheek nearest to you.
- With your other hand, grasp the far leg just above the knee and pull it up, keeping the foot on the ground.
- Keeping his hand pressed against his cheek, pull on the far leg to roll the victim towards you on to his side.
- Adjust the upper leg so that both the hip and knee are bent at right angles.
- Tilt the head back to make sure that the airway remains open.
- If necessary, adjust the hand under the cheek to keep the head tilted and facing downwards to allow liquid material to drain from the mouth.
- Check breathing regularly.

If the victim has to be kept in the recovery position for **more than 30 min** turn him to the opposite side to relieve the pressure on the lower arm.

Choking

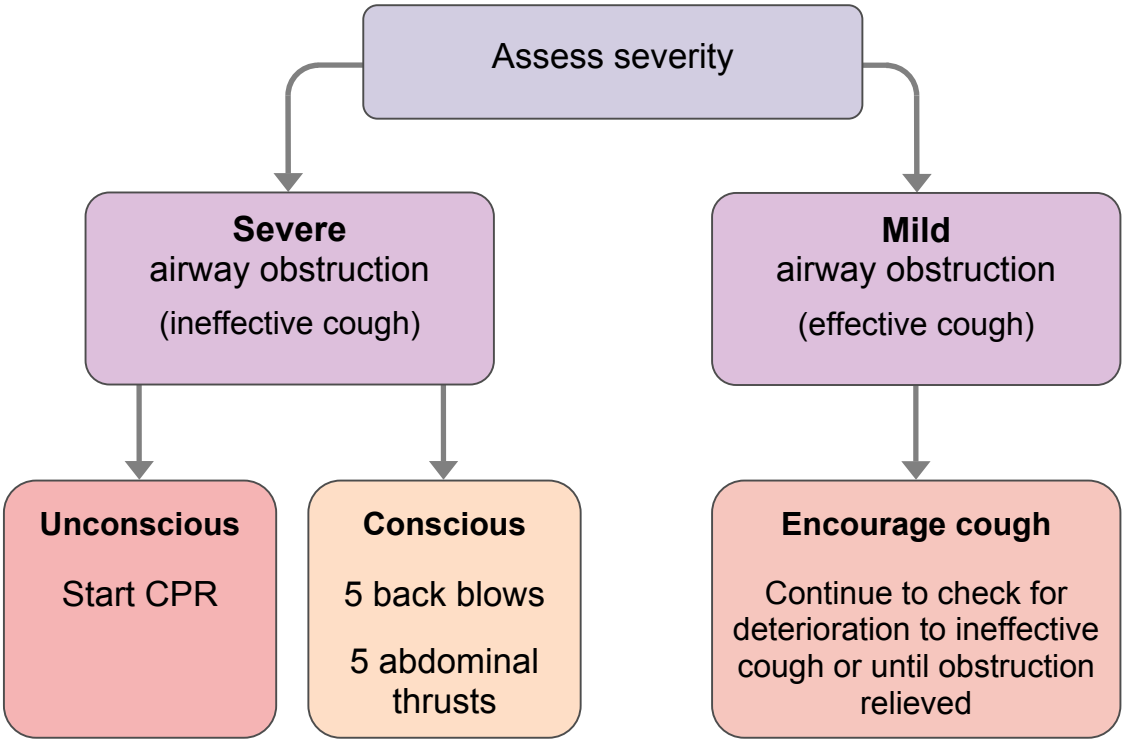
Recognition

Because recognition of choking (airway obstruction by a foreign body) is the key to successful outcome, it is important not to confuse this emergency with fainting, heart attack, seizure, or other conditions that may cause sudden respiratory distress, cyanosis, or loss of consciousness.

Foreign bodies may cause either mild or severe airway obstruction. The signs and symptoms enabling differentiation between mild and severe airway obstruction are summarised in the table below. It is important to ask the conscious victim 'Are you choking?'

<table>
<tr><th colspan="2">General signs of choking</th></tr>
<tr><td colspan="2">• Attack occurs while eating
• Victim may clutch his neck</td></tr>
<tr><th>Signs of severe airway obstruction</th><th>Signs of mild airway obstruction</th></tr>
<tr><td>Response to question 'Are you choking?'
• Victim unable to speak
• Victim may respond by nodding
Other signs
• Victim unable to breathe
• Breathing sounds wheezy
• Attempts at coughing are silent
• Victim may be unconscious</td><td>Response to question 'Are you choking?'
• Victim speaks and answers yes
Other signs
• Victim is able to speak, cough, and breathe</td></tr>
</table>

Adult choking treatment algorithm



Sequence for the treatment of adult choking

(This sequence is also suitable for use in children over the age of 1 year)

1. **If the victim shows signs of mild airway obstruction:**
   - Encourage him to continue coughing, but do nothing else.

2. **If the victim shows signs of severe airway obstruction and is conscious:**
   - Give up to five back blows.
     - Stand to the side and slightly behind the victim.
     - Support the chest with one hand and lean the victim well forwards so that when the obstructing object is dislodged it comes out of the mouth rather than goes further down the airway.
     - Give **up to** five sharp blows between the shoulder blades with the heel of your other hand.

- Check to see if each back blow has relieved the airway obstruction. The aim is to relieve the obstruction with each blow rather than necessarily to give all five.
- If five back blows fail to relieve the airway obstruction give up to five abdominal thrusts.
    - Stand behind the victim and put both arms round the upper part of his abdomen.
    - Lean the victim forwards.
    - Clench your fist and place it between the umbilicus (navel) and the bottom end of the sternum (breastbone).
    - Grasp this hand with your other hand and pull sharply inwards and upwards.
    - Repeat up to five times.
- If the obstruction is still not relieved, continue alternating five back blows with five abdominal thrusts.

3. If the victim becomes unconscious:

- Support the victim carefully to the ground.
- Call an ambulance immediately.
- Begin CPR (from 5B of the adult BLS sequence). Healthcare providers, trained and experienced in feeling for a carotid pulse, should initiate chest compressions even if a pulse is present in the unconscious choking victim.

Following successful treatment for choking, foreign material may nevertheless remain in the upper or lower respiratory tract and cause complications later. Victims with a persistent cough, difficulty swallowing, or with the sensation of an object being still stuck in the throat should therefore be referred for an immediate medical opinion.

Resuscitation of children and victims of drowning

Both ventilation and compression are important for victims of cardiac arrest when the oxygen stores become depleted: about 2 - 4 min after collapse from ventricular fibrillation (VF), and immediately after collapse for victims of asphyxial arrest. Previous guidelines tried to take into account the difference in causation, and recommended that victims of identifiable asphyxia (drowning; trauma; intoxication) and children should receive 1 min of CPR before the lone rescuer left the victim to get help. But most cases of sudden cardiac arrest out of hospital occur in adults and are of cardiac origin due to VF (even though many of these will have changed to a non-shockable rhythm by the time of the first rhythm analysis). These additional recommendations, therefore, added to the complexity of the guidelines whilst applying to only a minority of victims.

Many children do not receive resuscitation because potential rescuers fear causing harm. This fear is unfounded; it is far better to use the adult BLS sequence for resuscitation of a child than to do nothing. For ease of teaching and retention, laypeople

should be taught to use the adult sequence for children who are not responsive and not breathing normally, with the single modification that the chest should be compressed by one third of its depth. However, the following minor modifications to the adult sequence will make it even more suitable for use in children:

- Give 5 initial rescue breaths before starting chest compressions (adult BLS sequence of actions 5B).
- If you are on your own, perform CPR for 1 min before going for help.
- Compress the chest by one third of its depth. Use two fingers for an infant under 1 year; use one or two hands for a child over 1 year as needed to achieve an adequate depth of compression.

The same modifications of five initial breaths, and 1 min of CPR by the lone rescuer before getting help, may improve outcome for victims of drowning. This modification should be taught only to those who have a specific duty of care to potential drowning victims (e.g. lifeguards). If supplemental oxygen is available, and can be brought to the victim and used without interruption in CPR (e.g., by attaching to a resuscitation face mask), it may be of benefit.

Drowning is easily identified. It can be difficult, on the other hand, for a layperson to recognise when trauma or intoxication has caused cardiorespiratory arrest. If either cause is suspected the victim should be managed according to the standard BLS protocol.

Work Smart Session - MRCP Part 1

Time taken:

Question: 1 of 10

A 59-year-old woman attends the clinic three months after suffering an NSTEMI. Her BMI is 31.7kg/m^2.

Which of the following would you recommend to her?

(Please select 1 option)

- Clopidogrel
- Folic acid
- HRT
- 60 minutes of exercise every day
- Vitamin E supplementation

Work Smart Session - MRCP Part 1

Time taken: 25 mins 32 secs

Question: 10 of 10

A lifelong non-smoker is diagnosed with emphysema.

Which of the following would be the most likely aetiological agent ?

(Please select 1 option)

○	Asbestos
◉	Cadmium exposure ✓ Correct
○	Isocyanates
○	Steel
○	Zinc

Cadmium fume inhalation is a recognised cause of emphysema.

Other industrial associations with chronic obstructive pulmonary disease (COPD) include

- Coal
- Cotton
- Grain and
- Cement

A 59-year-old woman attends the clinic three months after suffering an NSTEMI. Her BMI is 31.7kg/m^2.

Which of the following would you recommend to her?

(Please select 1 option)

◉	Clopidogrel ✕ Incorrect answer selected
○	Folic acid
○	HRT
○	60 minutes of exercise every day ← This is the correct answer
○	Vitamin E supplementation

Guidelines have been published in Circulation (Early release - Circulation Feb 19th 2007) regarding cardiovascular risk reduction in women.

This particular woman has had an NSTEMI (Non-ST segment elevation MI) and is therefore at high risk.

The guidelines state that aspirin should not be used as primary prevention in women under 65, and then only if the benefits outweigh the risks.

Hormone replacement therapy (HRT), oestrogen modulators, folic acid, and antioxidant supplements (Vitamins D and E, and beta-carotene), are all designated as class III recommendations, that is they are considered not useful or even harmful.

The guidelines suggest at least 30 minutes of exercise per day, and to achieve weight goals they suggest 60-90 minutes of aerobic exercise per day.

Clopidogrel is advised only if patients are intolerant of aspirin.

A 24-year-old man presented with exertional thigh cramps. He described his urine turning to burgundy colour especially after prolonged exertion.

Investigations in the recent past had excluded the presence of any significant ischaemic or inflammatory condition affecting his lower limbs.

On examination, his pulse was 74 beats per minute, blood pressure was 122/66 mmHg, heart sounds were normal and there was no abnormal enlargement of any organ found on abdominal examination.

Investigations revealed:

Serum urea	4.4 mmol/L (2.5-7.5)
Serum creatinine	88 mol/L (60-110)
Serum corrected calcium	2.32 mmol/L (2.2-2.6)
Serum phosphate	1.3 mmol/L (0.8-1.4)
Serum creatine kinase	88 U/L (24-195)
Urine test	positive for myoglobulin

What is the most likely diagnosis?

(Please select 1 option)

- ○ Acute intermittent porphyria
- ○ Alkaptonuria
- ○ Gaucher's disease
- ○ Glycogen storage disease
- ○ Multiple myeloma

Work Smart Session - MRCP Part 1

Time taken: 17 mins 45 secs

Question: 3 of 10

A 53-year-old male is receiving treatment with imatinib for chronic myeloid leukaemia.

Which of the following is imatinib?

(Please select 1 option)

- Inhibits guanylate cyclase
- Inhibits HER
- Inhibits MAP kinase
- Inhibits p53
- Inhibits tyrosine kinase ✓ Correct

Imatinib is an inhibitor of tyrosine kinase and is used in the treatment of conditions such as chronic myelocytic leukaemia (CML) and gastrointestinal stromal tumours (GIST).

It inhibits TK on abl proto-oncogene, c-kit and the PDGF-R.

In CML, the Philadelphia chromosome leads to a fusion protein of abl with bcr (breakpoint cluster region), termed bcr-abl. As this is now a continuously active tyrosine kinase, imatinib is used to decrease bcr-abl activity.

Work Smart Session - MRCP Part 1

Time taken: 17 mins 45 secs

Question: 4 of 10

A 25-year-old female who is 20 weeks pregnant with her first child is admitted with palpitations.

The ECG reveals a supraventricular tachycardia (SVT) and this self terminates 20 minutes after admission. Subsequently she has further runs of symptomatic SVT.

What would be the most appropriate treatment for this patient's paroxysmal supraventricular tachycardia?

(Please select 1 option)

- Amiodarone
- Disopyramide
- Flecainide
- Metoprolol
- Verapamil

Question: 4 of 10

A 25-year-old female who is 20 weeks pregnant with her first child is admitted with palpitations.

The ECG reveals a supraventricular tachycardia (SVT) and this self terminates 20 minutes after admission. Subsequently she has further runs of symptomatic SVT.

What would be the most appropriate treatment for this patient's paroxysmal supraventricular tachycardia?

(Please select 1 option)

○	Amiodarone
○	Disopyramide
◉	Flecainide ✕ Incorrect answer selected
○	Metoprolol ← This is the correct answer
○	Verapamil

Tachyarrhythmias may increase during pregnancy although the causes are not entirely clear.

Regarding the termination of acute SVT, adenosine appears to be safe in pregnancy. In the case of the prevention of recurrent SVT then verapamil or beta -blockers have data supporting their use.

Current AHA/EHA criteria for the treatment of SVTs in pregnancy do suggest using metoprolol (level of evidence 1B) rather than verapamil (C), although they recommend avoiding the former in the first trimester.

Work Smart Session - MRCP Part 1

Time taken: 19 mins 20 secs

Question: 5 of 10

Which of the following most accurately describes the mechanism of action of the bisphosphonates?

(Please select 1 option)

- Calcium resorption in the distal tubule
- Fibroblast proliferation in bone marrow
- Improved vascular supply to bone marrow
- Inhibition of osteoclast activity
- Upregulation of osteoblast activity

Work Smart Session - MRCP Part 1

Time taken: 20 mins 3 secs

Question: 5 of 10

Which of the following most accurately describes the mechanism of action of the bisphosphonates?

(Please select 1 option)

- Calcium resorption in the distal tubule
- Fibroblast proliferation in bone marrow
- Improved vascular supply to bone marrow
- Inhibition of osteoclast activity ✓ Correct
- Upregulation of osteoblast activity

The mechanism of action of alendronate and risedronate as well as newer agents involves the inhibition of the pathway that leads to the production of certain essential lipid compounds inside osteoclasts.

This results in a series of events leading to decreased osteoclast activity and to the induction of cell death.

Work Smart Session - MRCP Part 1

Time taken: 20 mins 3 secs

Question: 6 of 10

A 55-year-old female who had a long history of alcohol abuse presents with diarrhoea and back pain one month after having a pacemaker inserted.

On examination she had a fever of 39°C and her abdomen was soft and non-tender.

What is the most likely diagnosis?

(Please select 1 option)

- Diverticulitis
- Ischaemic colitis
- Pancreatitis
- Pseudomembranous colitis
- Staphylococcal discitis

Work Smart Session - MRCP Part 1

Time taken: 20 mins 54 secs

Question: 6 of 10

A 55-year-old female who had a long history of alcohol abuse presents with diarrhoea and back pain one month after having a pacemaker inserted.

On examination she had a fever of 39°C and her abdomen was soft and non-tender.

What is the most likely diagnosis?

(Please select 1 option)

- ○ Diverticulitis
- ○ Ischaemic colitis
- ○ Pancreatitis
- ○ Pseudomembranous colitis
- ◉ Staphylococcal discitis ✓ Correct

All patients with alcohol dependence have an increased risk of pancreatitis, but this is less likely without any abdominal signs.

Ischaemic colitis classically presents with bloody diarrhoea.

The prophylactic antibiotics given four weeks previously for her pacemaker insertion would not really have predisposed her to pseudomembranous colitis.

Staphylococci are skin organisms most commonly introduced during pacemaker insertion and such a discitis would present with back pain.

Work Smart Session - MRCP Part 1

Time taken: 20 mins 54 secs

Question: 7 of 10

A 70-year-old male is admitted with haematemesis. He is currently being treated with warfarin for atrial fibrillation and his INR returns as 10 (<1.4).

Which of the following is the most appropriate immediate treatment of his INR?

(Please select 1 option)

- Cryoprecipitate
- Fresh frozen plasma
- Intravenous vitamin K
- Oral vitamin K
- Recombinant Factor VIII concentrate

Work Smart Session - MRCP Part 1

Time taken: 21 mins 44 secs

Question: 7 of 10

A 70-year-old male is admitted with haematemesis. He is currently being treated with warfarin for atrial fibrillation and his INR returns as 10 (<1.4).

Which of the following is the most appropriate immediate treatment of his INR?

(Please select 1 option)

- Cryoprecipitate
- Fresh frozen plasma ✓ Correct
- Intravenous vitamin K
- Oral vitamin K
- Recombinant Factor VIII concentrate

This patient has had a bleed related to a grossly elevated international normalised ratio (INR). Consequently the INR needs correction as rapidly as is possible.

Vitamin K will correct the INR over a few days, whereas fresh frozen plasma will correct the bleeding time rapidly.

Work Smart Session - MRCP Part 1

Time taken: 21 mins 44 secs

Question: 8 of 10

A 24-year-old man presented twelve hours after an overdose of dihydrocodeine 1.2 g and paracetamol 30 g.

He had pinpoint pupils, a Glasgow coma scale (GCS) score of 14 and a blood pressure of 100/60 mmHg.

Which one of the following is the most appropriate management?

(Please select 1 option)

- 500ml of 10% glucose intravenously over four hours.
- Intravenous flumazenil.
- Intravenous N-acetylcysteine.
- Intravenous naloxone.
- Oral activated charcoal.

Work Smart Session - MRCP Part 1

Time taken: 23 mins 38 secs

Question: 8 of 10

A 24-year-old man presented twelve hours after an overdose of dihydrocodeine 1.2 g and paracetamol 30 g.

He had pinpoint pupils, a Glasgow coma scale (GCS) score of 14 and a blood pressure of 100/60 mmHg.

Which one of the following is the most appropriate management?

(Please select 1 option)

○	500ml of 10% glucose intravenously over four hours.
○	Intravenous flumazenil.
○	Intravenous N-acetylcysteine. ← This is the correct answer
◉	Intravenous naloxone. ✕ Incorrect answer selected
○	Oral activated charcoal.

This patient's GCS is reasonable and the opiate-like effects seem minimal (no evidence of respiratory depression).

However, this patient has received a hefty dose of paracetamol conferring a high risk of hepatic toxicity. The 12 hour delay makes the absorptive effects of charcoal limited and although it would be useful as gastric emptying may be delayed it is not as important in this patient as the paracetamol antidote.

Even though the paracetamol level is not provided, he should be treated with N-acetylcysteine without delay.

Work Smart Session - MRCP Part 1

Time taken: 24 mins 34 secs

Question: 9 of 10

Which of the following symptoms is more suggestive of a functional disorder?

(Please select 1 option)

- Disorientation in time
- Inability to retain new information
- Mutism ← This is the correct answer
- Perseveration ✕ Incorrect answer selected
- Visual hallucinations

Functional refers to an illness that is without a structural defect.

Organic brain syndromes are physical conditions including structural brain disease and metabolic disturbances causing mental dysfunction.

Mutism is the most likely of the symptoms described to be associated with a functional disorder but is associated with schizophrenia or autism.

Time taken: 2 hrs 39 mins

Work Smart Session - MRCP Part 1

Question: 100 of 100

Which of the following may be responsible for a hypokalaemic hypertension?

(Please select 1 option)

○	Bartter's syndrome
○	Diabetic nephropathy
◉	Liddle's syndrome ✓ Correct
○	Non-classical congenital adrenal hyperplasia
○	Type IV renal tubular acidosis (RTA)

Liddle's syndrome is typically associated with hypokalaemic hypertension and low renin and aldosterone concentrations - the so-called pseudo-hyperaldosteronism.

Bartter's syndrome is associated with hypokalaemia, though hypertension is not a feature.

In type IV RTA, there is a hyporeninaemic hypoaldosteronism, which may also be produced with diabetic nephropathy, hence hyperkalaemia is more typical.

Question: 10 of 100

A 60-year-old woman has a systolic murmur.

As part of the evaluation you listen to the murmur during a Valsalva manoeuvre and the murmur becomes louder.

Which of the following systolic murmurs becomes louder with a Valsalva?

(Please select 1 option)

○	Aortic stenosis
◉	Hypertrophic obstructive cardiomyopathy ✓ Correct
○	Mitral flow murmur
○	Mitral regurgitation
○	Ventricular septal defect

Most murmurs of stenosis or regurgitation are exaggerated during squatting and get softer with the Valsalva manoeuvre.

The exceptions are hypertrophic cardiomyopathy (HOCM) where the opposite occurs and mitral valve prolapse where the murmur gets longer.

Question: 11 of 100

A 45-year-old man presents with a rash.

On examination you find he has eruptive xanthoma.

Which of the following is the most likely diagnosis?

(Please select 1 option)

○	Familial combined hyperlipidaemia
○	Familial hypercholesterolaemia
○	Familial hypertriglyceridaemia ← This is the correct answer
○	Hyperlipidaemia associated with nephrotic syndrome
◉	Remnant hyperlipidaemia ✕ Incorrect answer selected

Eruptive xanthomas occur in a number of types of hypertriglyceridaemia and also in uncontrolled diabetes mellitus.

Of those listed the most likely is familial hypertriglyceridaemia.

Work Smart Session - MRCP Part 1

Time taken: 16 mins

Question: 12 of 100

A 55-year-old man presents with severe dyspnoea with tachycardia and clinical examination raises the possibility that pericardial disease may be the cause.

Which of the following clinical features would favour cardiac tamponade rather than constrictive pericarditis?

(Please select 1 option)

○	Hypotension
○	Kussmaul's sign
○	Muffled heart sounds
◉	Pulsus paradoxus ✓ Correct
○	Raised JVP

In cardiac tamponade there is pulsus paradoxus (a greater than 10 mmHg fall in systolic BP on inspiration) but this is less commonly seen in constrictive pericarditis.

Kussmaul's sign (a rise in the jugular venous pressure [JVP] on inspiration) is more likely to be seen in constrictive pericarditis than cardiac tamponade.

Work Smart Session - MRCP Part 1

Time taken: 16 mins 47 secs

Question: 13 of 100

On physical examination a 65-year-old man is found to have pulsus alternans where there is regular alternation of the force of his radial pulse.

Which of the following conditions is the most likely diagnosis?

(Please select 1 option)

○	Aortic stenosis
○	Cardiac tamponade
○	Hypertrophic obstructive cardiomyopathy
○	Mixed aortic valve disease
◉	Severe left ventricular failure ✓ Correct

Pulsus alternans is a physical finding characterised by a regular alternation of the force of the arterial pulse.

It almost invariably indicates the presence of severe left ventricular systolic dysfunction.

NEJM 1996;334(13):834

Work Smart Session - MRCP Part 1

Time taken: 16 mins 47 secs

Question: 14 of 100

A 65-year-old man has been stable on the general medical ward following an admission with acute coronary syndrome several days previously.

His drug history consists of aspirin, enalapril and glyceryl trinitrate (GTN) spray. He has developed dyspnoea over the last few hours.

On examination he has a raised jugular venous pressure (JVP) and crackles to his mid zones. His electrocardiogram (ECG) shows a rate of 140 beats per minute in atrial fibrillation.

Which of the following is the most appropriate management?

(Please select 1 option)

○	IV amiodarone
○	IV digoxin
○	IV flecainide
○	Observe and screen for MI
◉	Synchronised DC cardioversion

Submit answer | Skip question | Tag Question | Remove question

His drug history consists of aspirin, enalapril and glyceryl trinitrate (GTN) spray. He has developed dyspnoea over the last few hours.

On examination he has a raised jugular venous pressure (JVP) and crackles to his mid zones. His electrocardiogram (ECG) shows a rate of 140 beats per minute in atrial fibrillation.

Which of the following is the most appropriate management?

(Please select 1 option)

○	IV amiodarone
○	IV digoxin
○	IV flecainide
○	Observe and screen for MI
◉	Synchronised DC cardioversion ✓ Correct

It is sometimes difficult to assess if the atrial fibrillation (AF) is a cause or a consequence of the heart failure in such a patient but the clinical history suggests that the AF has triggered the symptoms of left ventricular failure (LVF).

The best approach is therefore quickly to relieve the atrial fibrillation with cardioversion. This may not be possible, in which case a pharmacological approach may be tried.

A 17-year-old male presented with episodes of low back pain.

On clinical examination he is tall and has features of Marfan syndrome. You refer him for echocardiography and he asks why it is needed.

Which of the following is the most common abnormality seen in people with Marfan syndrome?

(Please select 1 option)

○	Bicuspid aortic valve
○	Coarctation of the aorta
◉	Dilation of the aortic sinuses ✓ Correct
○	Mitral valve prolapse
○	Primum atrial septal defect

"The normal aorta has three gentle bulges, the aortic sinuses, just distal to the semilunar attachments of the three leaflets of the aortic valve. The cross sectional diameter of the aorta at the nadir of the leaflet attachment where the aorta and ventricular muscle meet, and at the upper limit of the attachment at the sinutubular junction, are very similar, with the leaflets supported with a spatial relation as if to the sides of a cylinder. The diameter of the more distal circle at the sinutubular junction is, if anything, slightly smaller than the left ventricular outflow. This relation is lost in the Marfan syndrome. The aortic root becomes bulbous and the attachments of the leaflets are splayed out."
Heart 2000;84:674-678

Question: 17 of 100

A 24-year-old girl with Down syndrome is found on clinical examination to have a systolic murmur.

What is the most common cardiac defect seen in patients with Down syndrome that may explain this murmur?

(Please select 1 option)

◉	Endocardial cushion defect ✓ Correct
○	Mitral regurgitation
○	Patent ductus arteriosus
○	Secundum atrial septal defect
○	Ventricular septal defect

Endocardial cushion defects, more commonly known as atrioventricular (AV) canal or septal defects, include a range of defects characterised by involvement of the atrial septum, the ventricular septum, and one or both of the AV valves. (eMedicine)

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Work Smart Session - MRCP Part 1

Time taken: 21 mins 56 secs

Question: 19 of 100

A 50-year-old woman is found to have reversed splitting of the second heart sound.

This is found in which one of the following conditions?

(Please select 1 option)

○	Atrial septal (AS) defect
◉	Mild aortic regurgitation ✗ Incorrect answer selected
○	Patent ductus arteriosus ← This is the correct answer
○	Right bundle branch block (RBBB)
○	Ventricular septal defect (VSD)

Reversed splitting of the second heart sound occurs with reversal of the normal A2, P2 pattern.

Thus A2 may be delayed as with severe AS (not mild), and LBBB.

P2 may be early as with Wolff-Parkinson-White type B and persistent ductus arteriosus.

Atrial septal defects show wide fixed splitting, and RBBB has wide, but not fixed splitting.

Work Smart Session - MRCP Part 1

Time taken: 4 mins 58 secs

Question: 1 of 100

A 75-year-old woman presents with a two month history of episodic loss of vision in her right eye. Her electrocardiogram was normal and carotid ultrasound reveal a 50% stenosis of the right internal carotid artery.

What is the most appropriate treatment for this patient?

(Please select 1 option)

○	Aspirin ← This is the correct answer
○	Carotid endarterectomy
○	Dipyridamole
○	Prednisolone
◉	Warfarin ✕ Incorrect answer selected

The patient experienced transient ischaemic attacks (TIAs) of the form of amaurosis fugax due to carotid artery stenosis.

Carotid endarterectomy is only indicated if the stenosis is 70-99%.

Aspirin is the treatment of choice and good control of all vascular risk factors.

Warfarin is not indicated unless the patient is in atrial fibrillation (AF).

Work Smart Session - MRCP Part 1

Time taken: 4 mins 58 secs

Question: 2 of 100

Which one of the following is true regarding acute pulmonary embolism?

(Please select 1 option)

- A normal ECG excludes the diagnosis
- Embolectomy is more effective than thrombolysis in improving survival
- Heparin is as effective as thrombolytic therapy
- The presence of hypoxaemia is an indication for thrombolysis
- Thrombolysis administered through a peripheral vein is as effective as through a pulmonary artery catheter

Work Smart Session - MRCP Part 1

Time taken: 21 mins 56 secs

Question: 20 of 100

A 29-year-old female with Turner syndrome is referred by the GP concerned about her blood pressure which he has found to be persistently elevated at between 140-160/90 mmHg.

On examination she is noted to have a blood pressure of 148/92 mmHg, with no radio-femoral delay and no murmur audible.

Which of the following is the most likely cause of her hypertension?

(Please select 1 option)

○	Coarctation of the aorta
○	Essential hypertension
○	Primary hyperaldosteronism
○	Renal artery stenosis
○	Single horseshoe kidney

Submit answer | Skip question | Remove Tag | Remove question

A 29-year-old female with Turner syndrome is referred by the GP concerned about her blood pressure which he has found to be persistently elevated at between 140-160/90 mmHg.

On examination she is noted to have a blood pressure of 148/92 mmHg, with no radio-femoral delay and no murmur audible.

Which of the following is the most likely cause of her hypertension?

(Please select 1 option)

○	Coarctation of the aorta
◉	Essential hypertension ✓ Correct
○	Primary hyperaldosteronism
○	Renal artery stenosis
○	Single horseshoe kidney

Hypertension is quite common in Turner syndrome (10%) and is typically idiopathic - essential.

In a small proportion causes can include coarctation of the aorta and renal dysfunction due to horseshoe kidney.

In this case, essential hypertension is the most likely cause, but in the absence of specific features of coarctation this would again be the most appropriate option.

Work Smart Session - MRCP Part 1

Time taken: 23 mins 36 secs

Question: 21 of 100

A 62-year-old male who is being treated for stable angina presents with muscle aches and pains. He has been taking simvastatin 40 mg daily, atenolol 50 mg daily together with aspirin 75 mg daily for approximately two years. Recently he was admitted for an episode of acute coronary syndrome and a number of other therapies were added. You suspect a statin related myopathy and a CPK concentration is 820 iu/l (50-200).

Which of the following is most likely to be responsible for the precipitation of his statin related myopathy?

(Please select 1 option)

- Bisoprolol
- Clopidogrel
- Diltiazem
- Omega-3 fatty acids
- Spironolactone

Submit answer | Skip question | Tag Question | Remove question

A 62-year-old male who is being treated for stable angina presents with muscle aches and pains. He has been taking simvastatin 40 mg daily, atenolol 50 mg daily together with aspirin 75 mg daily for approximately two years. Recently he was admitted for an episode of acute coronary syndrome and a number of other therapies were added. You suspect a statin related myopathy and a CPK concentration is 820 iu/l (50-200).

Which of the following is most likely to be responsible for the precipitation of his statin related myopathy?

(Please select 1 option)

○	Bisoprolol
○	Clopidogrel
○	Diltiazem ← This is the correct answer
○	Omega-3 fatty acids
◉	Spironolactone ✕ Incorrect answer selected

Statin-associated myopathy occurs in up to 5% of those treated with statins and may be exacerbated by the co-prescription of other drugs such as calcium channel blockers, macrolide antibiotics, fibrates, amiodarone and grapefruit juice.

Whilst patients may tolerate a statin extremely well, a myopathy or rhabdomyolysis can quite esily be precipitated by the addition of these agents.

Work Smart Session - MRCP Part 1

Question: 22 of 100

A 45-year-old HIV-seropositive man attended the outpatient clinic for the results of a fasting serum lipid test.

He had been diagnosed with HIV disease two years previously and was started on highly active antiretroviral therapy. One year after commencing antiretrovirals, his CD4 count had risen from 10 cells/mm^3 to 120 cells/mm^3 with an undetectable viral load.

His current medications consisted of zidovudine, lamivudine, lopinavir, aciclovir, fluconazole and co-trimoxazole.

Fasting lipid profile revealed:

Serum cholesterol	4.1 mmol/l	(<5.2)
Serum triglyceride	18.2 mmol/l	(0.45-1.69)

Which of the following medications is most likely to be responsible for these results?

(Please select 1 option)

- ○ Co-trimoxazole
- ○ Fluconazole
- ○ Lamivudine
- ○ Lopinavir
- ○ Zidovudine

◉	Lopinavir ✓ Correct
○	Zidovudine

Lipodystrophy, lipoatrophy and alterations in serum lipid values have been observed in patients with human immunodeficiency virus (HIV) disease taking highly active antiretroviral therapy.

Elevated serum lipid levels have been associated with premature coronary artery disease.

Hypertriglyceridaemia is also thought to contribute to central fat deposition, and insulin resistance that is also seen in these patients.

Abnormalities of serum lipid levels are likely to be multifactorial in patients with HIV disease, but appear much commoner in patients taking protease inhibitors.

Isolated hypertriglyceridaemia can occur in HIV disease in the absence of protease inhibitors, but extremely high serum triglycerides have been documented in some patients treated with these drugs.

If the elevation in lipid levels is modest, measures such as dietary modification and exercise may be tried first. Omega-3 fish oils may also be beneficial in reducing modestly-elevated serum triglycerides.

In refractory cases, or where there is extreme isolated hypertriglyceridaemia, a fibrate should be used.

In addition, patients with HIV disease may also have elevated serum lipid levels due to familial hyperlipidaemia.

Work Smart Session - MRCP Part 1

Time taken: 27 mins 15 secs

Question: 23 of 100

A 41-year-old male on routine risk factor screening is noted to have a blood pressure of 146/86 mm/Hg.

His investigations reveal:

Fasting plasma glucose	5.8 mmol/L	(3.0-6.0)
Total cholesterol	6.2 mmol/L	(<5.2)
Triglyceride	12.8 mmol/L	(0.45-1.69)
HDL-cholesterol	0.8 mmol/L	(>1.55)

Which is the most appropriate treatment for his lipid profile?

(Please select 1 option)

- Ezetimibe
- Fenofibrate
- Nicotinic acid slow release
- Rosuvastatin
- Simvastatin

Submit answer | Skip question | Remove Tag | Remove question

HDL-cholesterol	0.8 mmol/L	(>1.55)

Which is the most appropriate treatment for his lipid profile?

(Please select 1 option)

○	Ezetimibe
○	Fenofibrate
○	Nicotinic acid slow release ← This is the correct answer
○	Rosuvastatin
◉	Simvastatin ✕ Incorrect answer selected

This patient is likely to have type V hyperlipoproteinaemia characterised by an excess of triglyceride containing lipoproteins and an increased risk of pancreatitis.

Nicotinic acid primarily reduces plasma TG levels via inhibition of hepatic TG synthesis suppressing FFA supply to the liver. It is currently the most effective TG reducing pharmacotherapy producing reductions of up to 30% in plasma TG at a dose of 2 g a day.

Its use is limited by side effects mainly flushing and an exacerbation of insulin resistance. The flushing may be diminished by gradual dose escalation, consumption following a low fat snack and concomitant aspirin use.

Alternative therapies in the event of intolerance to nicotinic acid include fenofibrate as a good second choice or alternatively omega-3 fatty acids.

Next question | Remove Tag | Remove question

EN 9:03 AM 2/28/2011

Question: 24 of 100

A 65-year-old male presents with arthralgia and sleep disturbance following the introduction of simvastatin.

He has a history of hypertension and ischaemic heart disease for which he is receiving aspirin, atenolol and eprosartan together with simvastatin 40 mg OD which has been introduced in the last one month. Previously, he had been taking atorvastatin but this was changed to simvastatin after he complained of arthralgia.

Investigations reveal:

Creatine phosphokinase (CPK)	156 U/l	(40-170)
Total cholesterol	5.1 mmol/l	(<5.2)
LDL-cholesterol	3.1 mmol/l	(<3.36)
Triglycerides	1.7 mmol/l	(0.45-1.69)
HDL-cholesterol	1.2 mmol/l	(>1.55)

Which is the most appropriate treatment for his lipid profile?

(Please select 1 option)

- Ezetimibe
- Fenofibrate
- Nicotinic acid slow release
- Omega-3 fatty acids
- Rosuvastatin

http://my.onexamination.com/Assessment/Que onexamination.com

(Please select 1 option)

○	Ezetimibe ← This is the correct answer
○	Fenofibrate
◉	Nicotinic acid slow release ✕ Incorrect answer selected
○	Omega-3 fatty acids
○	Rosuvastatin

The primary treatment target in this case is a total cholesterol (TC) less than 4 mmol/l and low-density lipoprotein cholesterol (LDL C) less than 2 mmol/l. Plasma triglyceride and high-density lipoprotein cholesterol (HDL-C) are already at the currently accepted target levels.

This patient describes typical statin-associated side effects which are generally a class effect and dose related. The most common adverse event with statin therapy is arthralgia or myopathy, often with normal CPK levels. Myositis and rhabdomyolysis are rare statin-associated myopathy side effects and are defined on the basis of CPK levels greater than 10x normal along with features of muscle pain and myoglobinuria (for rhabdomyolysis).

Risk factors predisposing to statin myopathy include advanced age, trauma, thyroid dysfunction and concomitant medication that can raise statin bioavailability including amiodarone, verapamil and many other agents that are metabolised by the cytochrome P450 enzyme system.

Ezetimibe monotherapy produces reductions in TC and LDL-C of around 20%, and since tolerability issues are likely to occur with another statin ezetimibe is the best treatment option.

Clinical trial data have demonstrated continuing event rate reduction to LDL-C levels below 2 mmol/l, and a meta-analysis of lipid lowering trials has demonstrated a 1 mmol/l reduction in LDL-C is associated with a 23% RRR in CHD events, irrespective of baseline risk and the method of cholesterol reduction.

EN 9:07 AM 2/28/2011

Work Smart Session - MRCP Part 1

Time taken: 33 mins 11 secs

Question: 25 of 100

A 55-year-old male with ischaemic heart disease is seen for review. He reports that he has developed some muscle aches and pains and you attribute this to a myalgia associated with simvastatin.

His creatinine kinase is within the normal range. However, his dyslipidaemia is still sub-optimal and you wish to add in a further agent.

Which of the following agents would not be an appropriate additional therapy for this patient in view of his presentation?

(Please select 1 option)

○	Cholestyramine
○	Ezetimibe
○	Gemfibrozil
○	Nicotinic acid
○	Omega-3 fatty acids

Submit answer | Skip question | Tag Question | Remove question

presentation?

- Shop

(Please select 1 option)

○	Cholestyramine
○	Ezetimibe
◉	Gemfibrozil ✓ Correct
○	Nicotinic acid
○	Omega-3 fatty acids

This patient presents with a probable statin-induced myalgia which often improves with time. Sometimes stopping therapy briefly or re-introducing a different statin may resolve the myalgia.

Statin-induced myositis is relatively uncommon, occurring in approximately 0.1-0.2%, but the risk of myositis and the potentially fatal rhabdomyolysis is increased with gemfibrozil in prone subjects in combination with a statin, and as such should be avoided.

Additional agents could include omega-3 fatty acids and ezetimibe.

Nicotinic acid is less used, due to problems with flushing though it can be useful particularly in hypertriglyceridaemia.

Cholestyramine can also be used.

Work Smart Session - MRCP Part 1

Time taken: 34 mins 4 secs

Question: 26 of 100

A 25-year-old female who is 20 weeks pregnant with her first child is admitted with palpitations.

The ECG reveals a supraventricular tachycardia (SVT) and this self terminates 20 minutes after admission. Subsequently she has further runs of symptomatic SVT.

What would be the most appropriate treatment for this patient's paroxysmal supraventricular tachycardia?

(Please select 1 option)

- Amiodarone
- Disopyramide
- Flecainide
- Metoprolol
- Verapamil

Submit answer | Skip question | Remove Tag | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 25-year-old female who is 20 weeks pregnant with her first child is admitted with palpitations.

The ECG reveals a supraventricular tachycardia (SVT) and this self terminates 20 minutes after admission. Subsequently she has further runs of symptomatic SVT.

What would be the most appropriate treatment for this patient's paroxysmal supraventricular tachycardia?

(Please select 1 option)

○	Amiodarone
○	Disopyramide
○	Flecainide
◉	Metoprolol ✓ Correct
○	Verapamil

Tachyarrhythmias may increase during pregnancy although the causes are not entirely clear.

Regarding the termination of acute SVT, adenosine appears to be safe in pregnancy. In the case of the prevention of recurrent SVT then verapamil or beta-blockers have data supporting their use.

Current AHA/EHA criteria for the treatment of SVTs in pregnancy do suggest using metoprolol (level of evidence 1B) rather than verapamil (C), although they recommend avoiding the former in the first trimester.

Question: 27 of 100

A 62-year-old male is admitted with an inferior myocardial infarction (MI) and receives thrombolysis, aspirin, atenolol, simvastatin and lisinopril. His ECG shows good ST segment resolution.

The following day he develops some pain in the legs and a dusky discolouration of the lower limbs. On closer examination there is a diffuse petechial rash over the lower legs, particularly the feet, but all peripheral pulses are palpable.

Investigations reveal:

Haemoglobin	13.3 g/dl	(12-16)
Platelets	145 x 10^9/l	(150-400)
White cell count	12.1 x 10^9/l	(4-11)
Neutrophils	6.5 x 10^9/l	(1.5-7)
Lymphocytes	3.5 x 10^9/l	(1.5-4)
Eosinophils	1.2 x 10^9/l	(0.04-0.4)
IgE antibody	3 kU/l	(<2)

Which of the following is the most likely cause for his current problems?

(Please select 1 option)

- ○ Allergic reaction to thrombolysis
- ○ Aspirin allergy
- ○ Cholesterol emboli
- ○ Peripheral vascular disease
- ○ Polyarteritis nodosa

Investigations reveal:

Haemoglobin	13.3 g/dl	(12-16)
Platelets	145 x 10^9/l	(150-400)
White cell count	12.1 x 10^9/l	(4-11)
Neutrophils	6.5 x 10^9/l	(1.5-7)
Lymphocytes	3.5 x 10^9/l	(1.5-4)
Eosinophils	1.2 x 10^9/l	(0.04-0.4)
IgE antibody	3 kU/l	(<2)

Which of the following is the most likely cause for his current problems?

(Please select 1 option)

◉	Allergic reaction to thrombolysis ✕ Incorrect answer selected
○	Aspirin allergy
○	Cholesterol emboli ← This is the correct answer
○	Peripheral vascular disease
○	Polyarteritis nodosa

This patient is an arteriopath as suggested by the acute MI, and one day after thrombolysis develops this petechial rash in the lower limbs with raised white cell count - marked eosinophilia and raised IgE.

Rather than allergy, this suggests cholesterol embolisation syndrome.

Work Smart Session - MRCP Part 1

Time taken: 37 mins 51 secs

Question: 28 of 100

A 67-year-old man with insulin-dependent diabetes with a broad complex pulseless tachyarrhythmia (with a protected airway) has been defibrillated three times.

He has just finished receiving two minutes of cardiopulmonary resuscitation (CPR) and has received adrenaline.

Which of the following is the next step in the management of the arrest?

(Please select 1 option)

○	Adrenaline 1 mg
○	Amiodarone 300 mg
○	DC shock
○	Lidocaine 100 mg
○	Removal of oxygen and then DC shock

Time taken: 40 mins 15 secs

Question: 28 of 100

A 67-year-old man with insulin-dependent diabetes with a broad complex pulseless tachyarrhythmia (with a protected airway) has been defibrillated three times.

He has just finished receiving two minutes of cardiopulmonary resuscitation (CPR) and has received adrenaline.

Which of the following is the next step in the management of the arrest?

(Please select 1 option)

○	Adrenaline 1 mg
◉	Amiodarone 300 mg ✓ Correct
○	DC shock
○	Lidocaine 100 mg
○	Removal of oxygen and then DC shock

After three DC shocks and a further cycle of two minutes of CPR the next step is amiodarone 300 mg intravenously and then a fourth shock.

If amiodarone is not available lidocaine is a suitable alternative.

Time taken: 40 mins 50 secs

Work Smart Session - MRCP Part 1

Question: 29 of 100

A 66-year-old man with insulin-dependent diabetes with a treated potassium of 5.4 mmol/l (3.5-5) and palpitations develops pulseless ventricular tachycardia. The anaesthetist is supporting airway and breathing.

Which of the following is the next step in his management?

(Please select 1 option)

○	Adrenaline 1 mg
○	Amiodarone 300 mg
○	Cardiopulmonary resuscitation (CPR) 15:2 for two minutes
○	Defibrillation at 150J biphasic ← This is the correct answer
◉	Praecordial thump ✕ Incorrect answer selected

In the case of ventricular tachycardia and ventricular fibrillation immediate defibrillation is the treatment of choice.

The other options come further down the algorithm and CPR is now recommended at 30:2.

A praecordial thump can be administered immediately following a witnessed cardiac arrest.

Work Smart Session - MRCP Part 1

Time taken: 5 mins 37 secs

Question: 2 of 100

Which one of the following is true regarding acute pulmonary embolism?

(Please select 1 option)

○	A normal ECG excludes the diagnosis
○	Embolectomy is more effective than thrombolysis in improving survival
○	Heparin is as effective as thrombolytic therapy
○	The presence of hypoxaemia is an indication for thrombolysis
◉	Thrombolysis administered through a peripheral vein is as effective as through a pulmonary artery catheter ✓ Correct

Embolectomies are rarely done nowadays due to the excellent results with thrombolysis.

Thrombolytic therapy is reserved for those with severely compromised circulation (equally effective through peripheral vein or via catheter in pulmonary artery).

Heparin reduces risk of further embolism (anticoagulant) and reduces pulmonary vasoconstriction.

Mission statement

The Royal College of Physicians plays a leading role in the delivery of high quality patient care by setting standards of medical practice and promoting clinical excellence. We provide physicians in the United Kingdom and overseas with education, training and support throughout their careers. As an independent body representing over 20,000 Fellows and Members worldwide, we advise and work with government, the public, patients and other professions to improve health and healthcare.

The National Collaborating Centre for Chronic Conditions

The National Collaborating Centre for Chronic Conditions (NCC-CC) is a collaborative, multi-professional centre undertaking commissions to develop clinical guidance for the NHS in England and Wales. The NCC-CC was established in 2001. It is an independent body, housed within Clinical Standards Department at the Royal College of Physicians of London. The NCC-CC is funded by the National Institute for Health and Clinical Excellence (NICE) to undertake commissions for national clinical guidelines on an annual rolling programme.

Dr Michael Rudolf, NCC-CC (*Chair*)
Consultant Respiratory Physician, Ealing Hospital NHS Trust

Professor Gregory Lip, NCC-CC *(Clinical Advisor)*
Professor of Cardiovascular Medicine, University Department of Medicine, City Hospital, Birmingham

Mrs Lina Bakhshi, NCC-CC
Information Scientist, Royal College of Physicians of London

Professor John Camm, British Cardiac Society
Consultant Cardiologist, St. George's Hospital Medical School, London

Dr Mark Davis, Primary Care Cardiovascular Society
General Practitioner, Moorfield House Surgery, Leeds

Mr Richard Deacon, Royal College of Nursing
Senior Charge Nurse, Leeds Teaching Hospitals NHS Trust

Dr Richard Dewar, Royal College of Physicians of London
Consultant Physician in General & Elderly Care Medicine, Pontypridd and Rhondda NHS Trust

Dr Martin Fotherby, British Geriatrics Society
Senior Lecturer in Age and Stroke Medicine, University of Leicester

Dr Jane Fisher, NCC-CC
Project Manager, Royal College of Physicians of London

Mrs Bernadette Ford, NCC-CC
Information Scientist, Royal College of Physicians of London

Dr Michael Hughes, NCC-CC
Research Fellow/Project Manager, Royal College of Physicians of London

Professor Lalit Kalra, King's College London, invited as an expert in stroke medicine to attend GDG meetings 3, 4, 11 and 14
Consultant Stroke Physician, King's College Hospital NHS Trust, London

Mr Simon Kendall, Society of Cardiothoracic Surgeons, invited as an expert in cardiothoracic surgery to attend GDG meetings 4 and 7
Consultant Cardiothoracic Surgeon, James Cook University Hospital, Middlesbrough

Dr Clifford Mann, British Association for Emergency Medicine
Consultant in Accident and Emergency Medicine, Taunton and Somerset NHS Trust

Dr Duncan McRobbie, Royal Pharmaceutical Society
Principal Clinical Pharmacist, Guy's and St Thomas' NHS Foundation Trust, London

Mr Leo Nherera, NCC-CC
Health Economist, Royal College of Physicians of London

Dr Stephen Rogers, Royal College of General Practitioners
Senior Lecturer in Primary Care, University College, London

Dr Peter Rose, invited as an expert in haematology to attend GDG meetings 3 and 4
Consultant Haematologist, South Warwickshire General Hospitals NHS Trust

Mr Peter Rose, The Stroke Association
Patient/Carer Representative, Information Service Organiser for the East of England, The Stroke Association

Mrs Fiona Sayers, Royal College of Nursing
Nurse Practitioner, Frimley Park Hospital NHS Foundation Trust, Surrey

Mr David Smith, British Cardiac Patients Association
Patient/Carer Representative, Trustee, British Cardiac Patients Association

Dr Neil Sulke, British Cardiac Society
Consultant Cardiologist, East Sussex Hospitals NHS Trust, Eastbourne

Preface

The association of an irregular pulse with morbidity has been recognised since antiquity, and as long ago as 1628 William Harvey observed cardiac irregularity directly in animals. The modern emphasis on electrical demonstration of atrial fibrillation (AF) dates back a mere 100 years to the first publication by William Einthoven of an electrocardiogram showing the abnormality. Even the treatment of this disorder has a long and venerable history: William Withering published *An account of the foxglove and some of its medical uses* in 1785, and digoxin, the active extract of his remedy, remains in use today.

A patient developing AF in 2006 is faced with a wide array of potential therapies. A number of drugs can be employed to control the rapid heart rate, which is often an intrinsic part of AF; attempts can be made to restore sinus rhythm using drugs or direct current electrical shock; and an increasing number of surgical procedures are described. Despite the wide number of options available, there is an acknowledgement that AF is too frequently treated with the almost automatic prescription of monotherapy with digoxin: this is still a useful drug over 200 years on but the best option for only a minority of patients. This failure to appreciate or implement proper treatment options in such a common condition makes AF an excellent topic for a national clinical guideline.

The guideline covers aspects of diagnosis and the management of AF in a number of different circumstances. It covers paroxysmal, persistent and permanent AF, considers AF developing after surgical procedures, and offers advice on haemodynamically unstable AF. Many of the recommendations relate to control of AF and the important decision of whether to attempt to restore sinus rhythm or concentrate on control of the heart rate. In a linked set of recommendations, the importance of considering anticoagulation in all these patients is emphasised. This is sometimes neglected in clinical practice, but anticoagulation is of enormous potential benefit because of its role in stroke prevention, and one of the key recommendations in the guideline is that the risk of thromboembolism should be formally assessed. A simple clinical model that includes advice on appropriate prophylaxis is suggested for this purpose. Other key recommendations cover the use of the electrocardiogram in diagnosis, and the preference in most patients for beta-blockers or rate-limiting calcium antagonists over digoxin for rate control.

The work of producing the guideline has been in the hands of a Guideline Development Group (GDG) comprising a small team from the National Collaborating Centre for Chronic Conditions working together with patients and health professionals with particular interest and experience in the management of AF. They have used the available evidence and their own clinical and personal judgement to produce guidance that is both clinically relevant and methodologically sound.

The GDG has had to evaluate a large amount of evidence during this process, and debate on some of the recommendations has been lively. The members have been driven throughout by the desire to produce a guideline that will be of value throughout the NHS. I am grateful to them for their hard work and for their expertise, and I am confident that they have produced a guideline that deserves to meet that aim.

Dr Bernard Higgins MD FRCP
Director, National Collaborating Centre for Chronic Conditions

List of abbreviations

AF	Atrial fibrillation
ARR	Absolute risk reduction
AV	Atrioventricular
AVJ	Atrioventricular junction (also called atrioventricular node)
bid	Twice daily
BSA	Body surface area
CABG	Coronary artery bypass graft
CHF	Congestive heart failure
CI	Confidence interval
Class Ic	Vaughan-Williams Class Ic antiarrhythmic drug
Class II	Vaughan-Williams Class II antiarrhythmic drug
Class III	Vaughan-Williams Class III antiarrhythmic drug
cm	Centimetre
CTR	Cardiothoracic ratio
CV	Cardioversion
CXR	Chest X-ray
DC	Direct current
ECG	Electrocardiogram
ECV	Electrical cardioversion
GDG	Guideline Development Group
Hg	Mercury
ICD	Implantable cardioverter defibrillator
ICER	Incremental cost-effectiveness ratio
ICH	Intracranial haemorrhage
INR	International normalised ratio
IV	Intravenous
LAA	Left atrial appendage
LAA-A	Left atrial appendage area
LAA-V	Left atrial appendage flow velocity
LAD	Left atrial diameter (synonymous with left-atrial dimension)
LA	Left atrium
LBBB	Left bundle branch block
LMWH	Low molecular weight heparin
LV	Left ventricular
LVEDD	Left ventricular end diastolic diameter
LVESD	Left ventricular end systolic diameter
LVEF	Left ventricular ejection fraction

LVFS	Left ventricular fractional shortening
LVH	Left ventricular hypertrophy
M	Metre
mg	Milligram
MI	Myocardial infarction
mm	Millimetre
mmol	Joule
N	Number of study participants
NCC-CC	National Collaborating Centre for Chronic Conditions
NICE	National Institute for Health and Clinical Excellence
NNT	Numbers needed to treat
NPV	Negative predictive value
NR	Not reported
NS	Not statistically significant
NSAID	Non-steroidal anti-inflammatory drug
NSF	National service framework
NYHA	New York Heart Association (functional classification)
OR	Odds ratio
p	Probability of a result happening by chance rather than because of a genuine effect
PCV	Pharmacological cardioversion
PPV	Positive predictive value
PVI	Pulmonary vein isolation
QALY	Quality-adjusted life-years
qid	Four times daily
RA	Right atrium
RAA	Right-atrial appendage
RBBB	Right bundle branch block
RCT	Randomised controlled trial
RR	Relative risk
sec	Second
SVT	Supraventricular tachycardia
TDP	Torsades des pointes
TEE	Thromboembolic event
TIA	Transient ischaemic attack
tid	Three times daily
TOE	Transoesophageal echocardiogram
TTE	Transthoracic echocardiogram
UK	United Kingdom
WMI	Wall motion index
WPW	Wolff–Parkinson–White syndrome

DEVELOPMENT OF THE GUIDELINE

1 Introduction

1.1 Definition

Atrial fibrillation (AF) is an atrial tachyarrhythmia characterised by predominantly uncoordinated atrial activation with consequent deterioration of atrial mechanical function. Another closely related atrial arrhythmia is atrial flutter, and this will also be discussed in the guideline insofar as its treatment coincides with that of AF itself.

On the electrocardiogram, AF is described by the absence of consistent P waves; instead there are rapid oscillations or fibrillatory waves that vary in size, shape and timing and are generally associated with an irregular ventricular response when atrioventricular (AV) conduction is intact. The patient may experience AF as palpitations, chest pain, dizziness, or in extreme cases loss of consciousness. In many cases, however, it may occur asymptomatically.

The ventricular response in AF depends on many things, including AV nodal properties, the level of vagal and sympathetic tone and drugs that affect AV nodal conduction such as beta-blockers, non-dihydropyridine calcium-channel blockers (calcium antagonists) and digitalis glycosides. However, regular relative risk (RR) intervals on the electrocardiogram (ECG) may occur, for example, in the presence of heart block associated with conduction disease or drug therapy. In patients with permanent ventricular pacing, the diagnosis may require temporary pacemaker inhibition in order to visualise AF activity. A rapid, irregular, sustained, wide QRS complex tachycardia could suggest AF with conduction via an accessory pathway.

1.2 Classification

Recent guidelines suggest classification of AF based on the temporal pattern of the arrhythmia (see Table 1.1).

Table 1.1 Classification of AF subtypes

Terminology	Clinical features	Pattern
Initial event (first detected episode)	Symptomatic Asymptomatic (first detected) Onset unknown (first detected)	May or may not reoccur
Paroxysmal	Spontaneous termination <7 days and most often <48 hours	Recurrent
Persistent	Not self-terminating Lasting >7 days or prior cardioversion	Recurrent
Permanent ('Accepted')	Not terminated Terminated but relapsed No cardioversion attempt	Established

Table reprinted with permission from Levy S, Camm AJ, Saksena S et al. International consensus on nomenclature and classification of atrial fibrillation. *Europace* 2003;5:119–22.[1]

AF is considered *recurrent* when a patient experiences two or more episodes. These episodes may be paroxysmal if they terminate spontaneously, defined by consensus as 7 days, or persistent if the arrhythmia requires electrical or pharmacological cardioversion for termination. Successful termination of AF does not alter the classification of persistent AF in these patients.

Long-standing AF (defined as over a year) that is not successfully terminated by cardioversion, or when cardioversion is not pursued, is classified as permanent.

Paroxysmal AF, in which the frequency of paroxysms is low, may degenerate into either paroxysmal AF with more frequent paroxysms, or a sustained form of AF. Similarly, persistent AF may degenerate into permanent AF. Despite its name, the reversion of permanent AF to normal sinus rhythm is also possible, particularly in those cases where the AF is caused by an underlying disease process which is successfully treated (eg thyroid disease), or where a specialist procedure is performed that modifies the electrophysiological properties of the heart.

Without treatment, AF can sometimes result in a degree of haemodynamic instability which can represent a critical condition that requires immediate intervention to alleviate symptoms of breathlessness, chest pain and loss of consciousness, and restore haemodynamic stability.

1.3 Epidemiology

1.3.1 Prevalence

AF is the commonest sustained cardiac arrhythmia. Much of the epidemiology of AF is derived from data from predominantly white populations, and information on AF in non-white populations is scarce. Hospital practice data may give a biased view of the clinical epidemiology of AF, since only one-third of patients with AF may actually have been admitted to hospital.[2]

The prevalence of AF roughly doubles with each advancing decade of age, from 0.5% at age 50–59 years to almost 9% at age 80–89 years.[3] Conversely, AF is very uncommon in infants and children, unless concomitant structural or congenital heart disease is present.

In the UK, the Renfrew–Paisley study[4] found that of an original cohort of men and women aged 45–64 years (N=15,406) there were 100 (0.65%; 95% CI 0.53 to 0.79%) documented cases of AF. The prevalence of AF increased with age and more cases were detected in men (53 of 7,052) than women (47 of 8,354)[4] as shown in Figure 1.1. In the West Birmingham AF project, the prevalence of AF was 2.4% in two general practices[2] and further extension of this project showed that the prevalence of AF among Indo-Asians aged over 50 years in the general practice population was 0.6%.[5] The Newcastle survey screened 4,843 people aged 65 years or more in general practices and found a prevalence of AF of 4.7%.[6] Among UK hospital admissions, AF is present in 3–6% of acute medical admissions.[7,8]

The 4-year incidence of AF in the Renfrew–Paisley project was 0.54 cases per 1,000 person years[4] (see Figure 1.2).

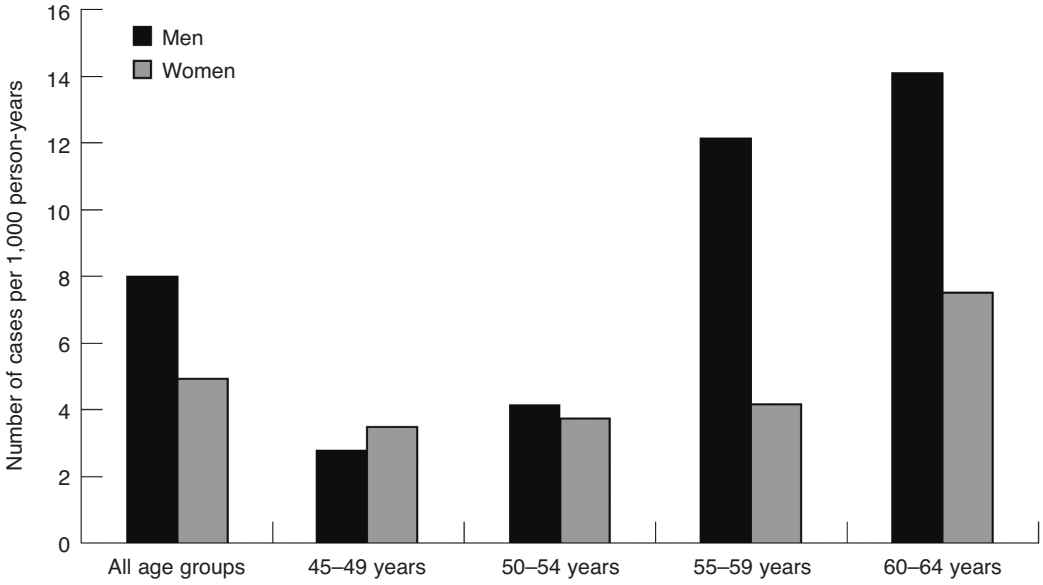

Figure 1.1 Prevalence of AF in the Renfrew–Paisley project.[4*]

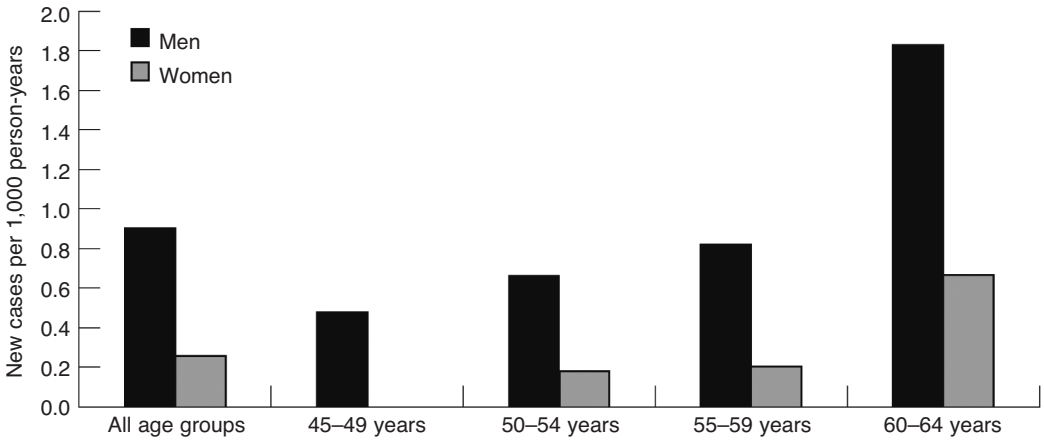

Figure 1.2 Incidence of AF in the Renfrew–Paisley project.[4] *Figures 1.1 and 1.2 were reproduced with permission of BMJ Publishing Ltd from Stewart S, Hart CL, Hole DJ et al. Population prevalence, incidence, and predictors of atrial fibrillation in the Renfrew/Paisley study. *Heart* (British Cardiac Society) 2001;86:516–21.

1.3.2 Risk factors

There are many risk factors for developing AF. As discussed above, there is an increasing prevalence and incidence of AF with increasing age. In the Framingham study[9] the development of AF was associated with increasing age (odds ratio (OR) 2.1 for men and 2.2 for women, $p < 0.0001$), diabetes (OR 1.4 for men and 1.6 for women), hypertension (OR 1.5 for men and 1.4 for women), and valve disease (OR 1.8 for men and 3.4 for women). It is also commonly associated with, and complicated by, congestive heart failure and strokes.

AF is often caused by coexisting medical conditions. These causes can be cardiac and non-cardiac (see Table 1.2).

Table 1.2 Common cardiac and non-cardiac causes of AF

Cardiac causes of AF	Non-cardiac causes of AF
Common cardiac causes: ischaemic heart disease rheumatic heart disease hypertension sick sinus syndrome pre-excitation syndromes (eg Wolff–Parkinson–White).	Acute infections, especially pneumonia
Less common cardiac causes: cardiomyopathy or heart muscle disease pericardial disease (including effusion and constrictive pericarditis) atrial septal defect atrial myxoma.	Electrolyte depletion
	Lung carcinoma
	Other intrathoracic pathology (eg pleural effusion)
	Pulmonary embolism
	Thyrotoxicosis

AF is also common after surgery, especially cardiothoracic operations such as thoracotomy and coronary artery bypass graft. Overall, the presence of the AF after surgery not only results in prolongation of hospital stay but may also increase risk of heart failure, stroke, or thromboembolism, and greater hospital costs. The incidence of postoperative AF depends on many risk factors apart from the type of procedure, such as age and the patient's preoperative physiology and electrolyte balance.

Many dietary and lifestyle factors have also been associated with AF. These include excessive alcohol or caffeine consumption and emotional or physical stress. In the case of alcohol, AF may develop as a consequence of an excessive intake of alcohol over a relatively short period – a so-called 'holiday heart'. In one series of younger patients (aged <65 years) with new onset AF, alcohol caused or contributed to the arrhythmia in 63% of cases.[10]

Lone AF is defined as AF without overt structural heart disease, and defined by a normal clinical history and examination, ECG, chest X-ray and, more recently, the echocardiogram. There are implications of labelling patients with this diagnosis, as this group is often considered to be at 'low risk', although recent data have been inconclusive.

A diagnosis of lone AF is only considered a diagnosis of exclusion if there is:

- no history of cardiovascular disease or hypertension
- no abnormal cardiac signs on physical examination
- a normal chest X-ray and, apart from the presence of AF, a normal ECG (ie no indication of prior myocardial infarction or left ventricular hypertrophy)
- normal atria, valves and left ventricular size and function by echocardiography.

1.4 Prognosis

The adverse effects of AF are the result of haemodynamic changes related to the rapid and/or irregular heart rhythm, and thromboembolic complications related to a prothrombotic state associated with the arrhythmia. AF is associated with an odds ratio for death of 1.5 for men and 1.9 in women, which does not vary by age, but most of the excess of mortality attributed to AF occurs early after diagnosis of AF.[11]

Onset of AF can result in a reduction in cardiac output of up to 10–20% regardless of ventricular rate. The presence of fast ventricular rates can push an already compromised ventricle into heart failure. An uncontrolled AF rate may even precipitate critical cardiac ischaemia.

AF is associated with a prothrombotic state – intra-atrial blood stasis, structural heart disease or blood vessel abnormalities and abnormal platelets and haemostasis – leading to a predisposition to thrombus formation (thrombogenesis).[12] This prothrombotic state predisposes to stroke and thromboembolism in AF, with an approximately five-fold greater risk than that of people without AF.[13] In stroke patients, concurrent AF is associated with greater disability, longer in-hospital patient stay and lower rate of discharge to own home. The incidence of strokes attributable to AF increases from 1.5% at age 50–59 years to 23.5% at age 80–89 years.[14]

In terms of the direct effects on patients' quality of life, AF can also result in reduced exercise tolerance, as well as impairment in cognitive function.

1.5 Guideline structure

Chapter 2 details the methodology used in the construction of this guideline. This includes the protocols used for the searching, selection and appraisal of evidence, and the grading of recommendations according to the strength of their supporting evidence.

The remaining chapters deal with specific issues in the diagnosis and treatment of AF. For ease of reference, wherever possible different forms of AF have been considered in distinct chapters, as follows:

- persistent AF (Chapter 6)
- permanent AF (Chapter 7)
- paroxysmal AF (Chapter 8)
- acute-onset AF (Chapter 9)
- postoperative AF (Chapter 10).

Most of these chapters include an easy-to-use flowchart showing the recommendations relevant to the particular form of AF.

There are also chapters dedicated to the identification and diagnosis of AF, as well as to antithrombotic therapy and cardioversion.

1.6 How to use this guideline

- The purpose of this guideline is to support clinical judgement, not to replace it. This means the treating clinician should:
  - take into consideration any contraindications in deciding whether or not to administer any treatment recommended by this guideline
  - consider the appropriateness of any recommended treatment for a particular patient in terms of the patient's relevant clinical and non-clinical characteristics.
- Wherever possible, before administering or changing any treatment the treating clinician should follow good practice in terms of:
  - discussing with the patient why the treatment is being offered and what health outcomes are anticipated
  - highlighting any possible adverse events or side effects that have been associated with the treatment
  - obtaining explicit consent for the treatment.
- For those recommendations involving pharmacological treatment, the most recent edition of the *British National Formulary* (**www.bnf.org.uk**) should be followed for the determination of:
  - indications
  - drug dosage
  - method and route of administration
  - contraindications
  - supervision and monitoring
  - product characteristics.

  Exceptions to the above are cases where guidance is provided within the recommendation itself.
- The guideline will normally only make drug recommendations that fall within licensed indications. If a drug is recommended outside of its licensed indication this will be made clear in the guideline (see Appendix D).

2 Methodology

2.1 About the guideline

2.1.1 Aim

With this document the National Collaborating Centre for Chronic Conditions (NCC-CC) has aimed to provide a user-friendly, clinical, evidence-based guideline for the National Health Service (NHS) in England and Wales that:

- offers best clinical advice for AF
- is based on best published evidence and expert consensus
- takes into account patient choice and informed decision-making
- defines the major components of NHS care provision for AF
- indicates areas suitable for clinical audit
- details areas of uncertainty or controversy requiring further research
- provides a choice of guideline versions for differing audiences.

2.1.2 Scope

The guideline was developed in accordance with a scope which detailed the remit of the guideline originating from the Department of Health and specified those aspects of AF to be included and excluded. Prior to the commencement of the guideline development, the scope was subjected to stakeholder consultation in accordance with processes established by the National Institute for Health and Clinical Excellence (NICE).[15] The full scope is shown in Appendix G.

This guideline sets out best practice for the diagnosis and treatment of AF in both primary and secondary care. It also considers which patients benefit from referral for specialist investigations or procedures and offers guidance in this respect.

Most of the recommendations made in this guideline apply to both AF and the closely related arrhythmia atrial flutter (in those cases where the two conditions are indistinguishable). Exceptions are recommendations concerning diagnosis and opportunistic case-detection, which apply only to AF.

Although the guideline covers the majority of AF cases, it does not consider those patients for whom there is a need for highly specialised clinical input. In particular, it does not consider paediatric cases of AF, or gestational AF.

With the exception of the use of prophylactic drugs to prevent postoperative AF and the use of typical symptoms in guiding opportunistic case-detection, the guideline will not consider issues of public health screening or interventions.

The guideline does not make any recommendations in terms of health service delivery for AF treatment, although it does consider the effectiveness of different service models. In particular, it considers the effectiveness of self-management of anticoagulation compared to clinic-based management, and the use of pill-in-the-pocket therapy compared with continuous drug therapy or emergency department treatment.

2.1.3 Audience

The guideline is intended for use by the following people or organisations:

- all healthcare professionals
- people with AF and their carers
- patient support groups
- commissioning organisations
- service providers.

2.1.4 Patient involvement

The NCC-CC was keen to ensure that the views and preferences of people with AF and their carers informed all stages of the guideline. This was achieved by:

- having a person with AF and a representative of a user organisation on the Guideline Development Group (GDG)
- consulting the Patient Information Unit (PIU) housed within NICE during the pre-development (scoping) and final validation stages of the guideline.

2.1.5 Guideline limitations

Limitations to the guideline are as follows:

- Clinical guidelines usually do not cover issues of service delivery, organisation or provision (unless specified in the remit from the Department of Health).
- NICE is primarily concerned with health services and so recommendations are not provided for social services and the voluntary sector. However, the guideline may address important issues in how NHS clinicians interface with these other sectors.
- Generally the guideline does not cover rare, complex, complicated or unusual conditions.

2.2 Guideline development

2.2.1 Background

The development of this evidence-based clinical guideline draws upon the methods described by the NICE *Guideline development methods* manual[16] (**www.nice.org.uk/page.aspx?o=201982**) and the methodology pack[17] specifically developed by the National Collaborating Centre for Chronic Conditions (NCC-CC) for each chronic condition guideline (**www.rcplondon.ac.uk/college/ceeu/ncccc_index.htm**). The developers' roles and remit are summarised below.

▷ National Collaborating Centre for Chronic Conditions

The NCC-CC was set up in 2001 and is housed within the Royal College of Physicians. The NCC-CC undertakes commissions received from the National Institute for Health and Clinical Excellence (NICE).

A multiprofessional partners' board inclusive of patient groups and NHS management governs the NCC-CC.

▷ NCC-CC technical team

The technical team met approximately two weeks before each GDG meeting and comprised:

- the GDG group leader
- the GDG clinical advisor
- an information scientist
- a research fellow
- a health economist
- a project manager
- administrative personnel.

▷ Guideline Development Group[16]

The GDG met 14 times between July 2004 and December 2005 and comprised a multidisciplinary team of professionals, service users (people with AF or carers), and user organisation representatives who were supported by the technical team.

The GDG membership details, including patient representation and professional groups, are listed at the front of this guideline (see pages vi–vii).

Members of the GDG declared any interests in accordance with the NICE technical manual.[16] A register is available from the NCC-CC for inspection upon request (**ncc-cc@rcplondon.ac.uk**).

▷ Sign-off workshop[17]

At the end of the guideline development process the GDG met to review and agree the guideline recommendations.

2.2.2 The guideline development process

There are ten basic steps in the process of producing a guideline.

▷ Step 1: Developing evidence-based questions

The technical team drafted a series of clinical questions that covered the guideline scope. The GDG and Project Executive refined and approved these questions, shown in Appendix C.

▷ Step 2: Systematically searching for the evidence

The information scientist developed a search strategy for each question. Key words for the search were identified by the GDG. In addition, the health economist searched for additional papers to inform detailed health economic work (eg modelling). Papers that were published or accepted for publication in peer-reviewed journals were considered as evidence by the GDG. Conference paper abstracts and non-English language papers were excluded from the searches.

Each clinical question dictated the appropriate study design that was prioritised in the search strategy but the strategy was not limited solely to these study types. The research fellow or health economist identified titles and abstracts from the search results that appeared to be

relevant to the question. Exclusion lists were generated for each question together with the rationale for the exclusion. The exclusion lists were presented to the GDG. Full papers were obtained where relevant. See Appendix C for literature search details.

▷ Step 3: Critically appraising the evidence

The research fellow or health economist, as appropriate, critically appraised the full papers. In general no formal contact was made with authors but there were *ad hoc* occasions when this was required in order to clarify specific details. Critical appraisal checklists were compiled for each full paper. One research fellow undertook the critical appraisal and data extraction. The evidence was considered carefully by the GDG for accuracy and completeness.

All procedures are fully compliant with:

- NICE methodology as detailed in the *Guideline development methods – information for National Collaborating Centres and guideline developers* manual.[16]
- NCC-CC quality assurance document and systematic review chart, available at **www.rcplondon.ac.uk/college/ceeu/ncccc_index.htm**

▷ Step 4: Incorporating health economic evidence

There were constraints in the health economic resources and so the following approach was agreed for this guideline. Health economics was incorporated alongside the clinical questions.

- Searches in relevant databases were done by the information scientist using economic filters on the related clinical questions.
- No study design criteria were imposed a priori, ie the searches were not limited to randomised control trials (RCTs) or formal economic evaluations.
- Titles and abstracts identified in the economic searches were reviewed by the health economist and full papers were obtained once they met the inclusion/exclusion criteria.
- The full papers were critically appraised by the health economist and the relevant data were presented to the GDG.

Cost-effectiveness evidence from the UK was preferred, but all relevant evidence was considered, including non-UK studies.

The GDG identified areas for additional economic work. Five key areas were identified and three were given priority. The GDG agreed on the model structures. The health economist performed supplemental literature searches using key search terms in Medline and an Internet search engine to obtain additional information for modelling. None of the identified priority areas were modelled for various reasons (see Appendix A for details).

▷ Step 5: Distilling and synthesising the evidence and developing recommendations

The evidence from each full paper was distilled into an evidence table and synthesised into evidence statements before being presented to the GDG. This evidence was then reviewed by the GDG and used as a basis upon which to formulate recommendations.[2]

▷ Step 6: Grading the evidence statements and recommendations

The criteria for grading evidence and classifying recommendations are shown in Table 2.1.

Evidence tables are available at
www.rcplondon.ac.uk/pubs/online_home.htm

Table 2.1 Criteria for grading evidence and recommendations. Note that diagnostic study levels of evidence and classification of recommendations were also included.[16]

Levels of evidence		Classification of recommendations	
Level	**Type of evidence**	**Class**	**Evidence**
1++	High-quality meta-analysis (MA), systematic reviews (SR) of randomised controlled trials (RCTs), or RCTs with a very low risk of bias.	A	Level 1++ and directly applicable to the target population *or* level 1+ and directly applicable to the target population **AND** consistency of results. Evidence from NICE technology appraisal.
1+	Well-conducted MA, SR or RCTs, or RCTs with a low risk of bias.		
1–	MA, SR of RCTs, or RCTs with a high risk of bias.	Not used as a basis for making a recommendation.	
2++	High-quality SR of case-control or cohort studies. High-quality case-control or cohort studies with a very low risk of confounding, bias or chance and a high probability that the relationship is causal.	B	Level 2++, directly applicable to the target population and demonstrating overall consistency of results. *or* extrapolated evidence from 1++ or 1+.
2+	Well-conducted case-control or cohort studies with a low risk of confounding, bias or chance and a moderate probability that the relationship is causal.		
2–	Case-control or cohort studies with a high risk of confounding, bias or chance and a significant risk that the relationship is not causal	Not used as a basis for making a recommendation.	
3	Non-analytic studies (for example case reports, case series).	C	Level 2+, directly applicable to the target population and demonstrating overall consistency of results *or* extrapolated evidence from 2++.
4	Expert opinion, formal consensus.	D	Level 3 or 4 *or* extrapolated from 2+ *or* formal consensus.
		D (GPP)	A good practice point (GPP) is a recommendation based on the experience of the GDG.

Diagnostic study level of evidence and classification of recommendation was also included.[2]

▷ Step 7: Agreeing the recommendations

The sign-off workshop employed formal consensus techniques to:

- ensure that the recommendations reflected the evidence base
- approve recommendations based on lesser evidence or extrapolations from other situations
- reach consensus recommendations where the evidence was inadequate
- debate areas of disagreement and finalise recommendations.

The sign-off workshop also reached agreement on the following:

- five priorities for implementation
- five key research recommendations
- algorithms.

In prioritising key recommendations for implementation, the sign-off workshop also took into account the following criteria:

- high clinical impact
- high impact on reducing variation
- more efficient use of NHS resources
- allowing the patient to reach critical points in the care pathway more quickly.

The audit criteria provide suggestions of areas for audit in line with the key recommendations for implementation.[16]

▷ Step 8: Structure of the guideline

The guideline is divided into sections for ease of reading. For most sections the layout is similar and is described below:

- The *clinical introduction* sets a succinct background and describes the current clinical context.
- The *methodological introduction* describes any issues or limitations that were apparent when reading the evidence base.
- *Evidence statements* provide a synthesis of the evidence base and usually describe what the evidence showed in relation to the outcomes of interest.
- *Health economics* presents, where appropriate, an overview of the cost effectiveness of the evidence base.
- *From evidence to recommendations* highlights the debate of the GDG. This section sets out the GDG decision-making rationale providing a clear and explicit audit trail from the evidence to the evolution of the recommendations.
- The *recommendations* section provides stand-alone, action-orientated recommendations.
- *Evidence tables* are not published as part of the full guideline but are available online at **www.rcplondon.ac.uk/pubs/books/af/** These describe comprehensive details of the primary evidence that was considered during the writing of each section.

▷ Step 9: Writing the guideline

The first draft version of the guideline was drawn up by the technical team in accordance with the decision of the GDG. The guideline was then submitted for two formal rounds of public and stakeholder consultation prior to publication.[16] The registered stakeholders for this guideline are detailed in Appendix F. Editorial responsibility for the full guideline rests with the GDG.

Table 2.2 describes the versions of the guideline that are available.

Table 2.2 Versions of this guideline

Full version	Details the recommendations. The supporting evidence base and the expert considerations of the GDG. Available at **www.rcplondon.ac.uk/pubs/online_home.htm**
NICE version	Documents the recommendations without any supporting evidence. Available at **www.nice.org.uk/page.aspx?o=guidelines.completed**
Quick reference guide	An abridged version. Available at **www.nice.org.uk/page.aspx?o=guidelines.completed**
Information for the public	A lay version of the guideline recommendations. Available at **www.nice.org.uk/page.aspx?o=guidelines.completed**

▷ Step 10: Updating the guideline

Literature searches were repeated for all of the evidence-based questions at the end of the GDG development process allowing any relevant papers published up until 30 June 2006 to be considered. Future guideline updates will consider evidence published after this cut-off date.

Two years after publication of the guideline, NICE will commission a National Collaborating Centre to determine whether the evidence base has progressed significantly to alter the guideline recommendations and warrant an early update. If not, the guideline will be updated approximately 4 years after publication.[16]

2.3 Disclaimer

Healthcare providers need to use clinical judgement, knowledge and expertise when deciding whether it is appropriate to apply guidelines. The recommendations cited here are a guide and may not be appropriate for use in all situations. The decision to adopt any of the recommendations cited here must be made by the practitioner in light of individual patient circumstances, the wishes of the patient, clinical expertise and resources.

The NCC-CC disclaims any responsibility for damages arising out of the use or non-use of these guidelines and the literature used in support of these guidelines.

2.4 Funding

The National Collaborating Centre for Chronic Conditions was commissioned by the National Institute for Health and Clinical Excellence to undertake the work on this guideline.

3 Key messages of the guideline

3.1 Priorities for implementation

The following five recommendations have been identified by the GDG as priorities for implementation:

1. An electrocardiogram (ECG) should be performed in all patients, whether symptomatic or not, in whom AF is suspected because an irregular pulse has been detected.
2. As some patients with persistent AF will satisfy criteria for either an initial rate-control or rhythm-control strategy (for example, aged over 65 but also symptomatic):
   - the indications for each option should not be regarded as mutually exclusive and the potential advantages and disadvantages of each strategy should be explained to patients before agreeing which to adopt
   - any comorbidities that might indicate one approach rather than the other should be taken into account
   - irrespective of whether a rate-control or a rhythm-control strategy is adopted in patients with persistent AF, appropriate antithrombotic therapy should be used.
3. In patients with permanent AF, who need treatment for rate control:
   - beta-blockers or rate-limiting calcium antagonists should be the preferred initial monotherapy in all patients
   - digoxin should only be considered as monotherapy in predominately sedentary patients.
4. In patients with newly diagnosed AF for whom antithrombotic therapy is indicated (see section 11.6), such treatment should be initiated with minimal delay after the appropriate management of comorbidities.
5. The stroke risk stratification algorithm (Figure 11.1) should be used in patients with AF to assess their risk of stroke and thromboembolism, and appropriate thromboprophylaxis given.

Each of these recommendations highlights areas of current clinical practice that the GDG believe would particularly benefit from guidance. Compliance with each of these key priority areas may be audited according to the corresponding audit criteria below.

Although items 4 and 5 may be audited using the same criteria, they address two different issues relating to antithrombotic therapy in AF. The first addresses the need for appropriate antithrombotic therapy in patients with AF upon initial diagnosis; the second addresses the need for a formal assessment of stroke risk and the administration of appropriate antithrombotic therapy based on that assessment.

3.2 AF care pathway

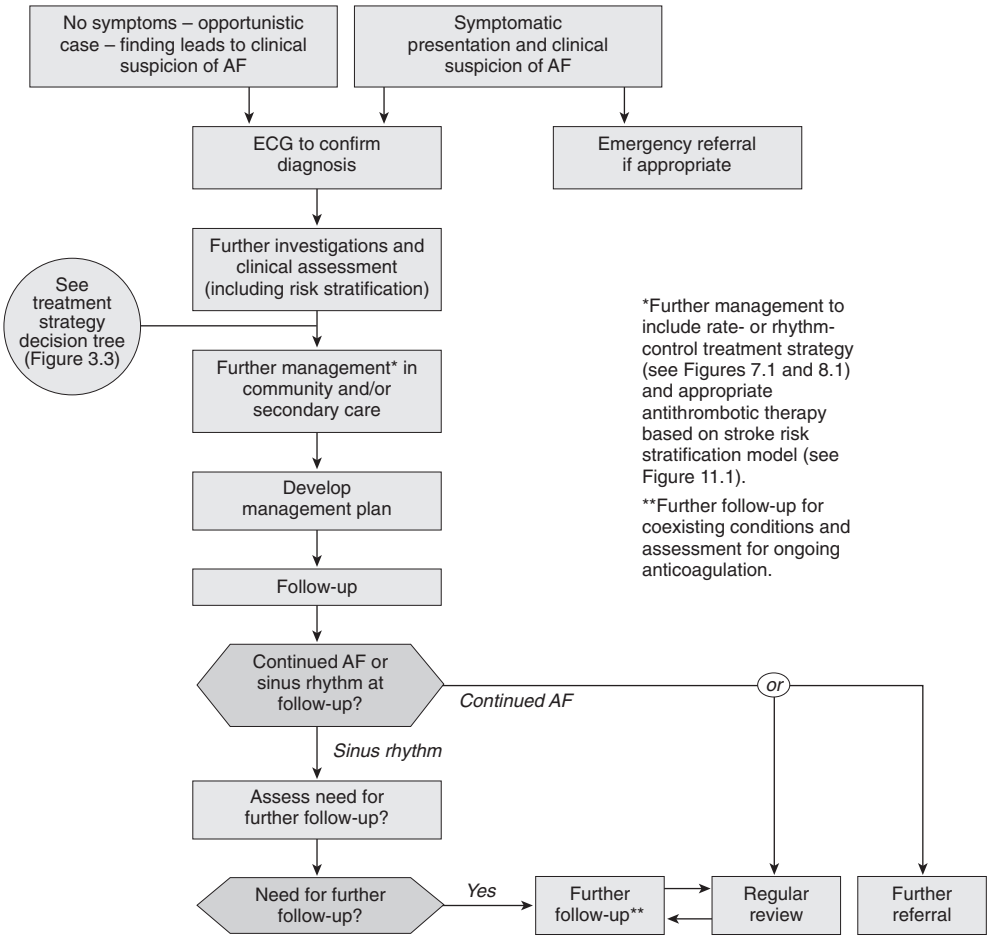

Figure 3.1 AF care pathway

3.3 Treatment strategy decision tree

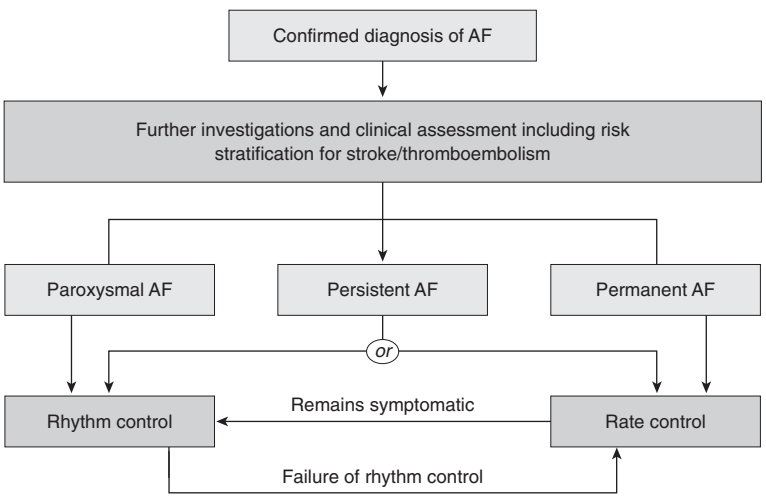

Figure 3.2 Treatment strategy decision tree

3.4 Audit criteria

Table 3.1 lists the audit criteria identified to evaluate the impact of the implementation of the five key priority areas detailed above on clinical practice and health outcomes.

Table 3.1 Audit criteria for the key priorities for implementation

Criterion	Exception	Definition of terms
1. All people presenting to primary or secondary care with a history of hypertension, heart failure, diabetes or stroke and noted to have an irregular pulse to be offered an ECG and any new diagnosis of AF recorded.	None.	Percentage of patient records with a new diagnosis of AF made following an ECG made on the basis of detection of an irregular pulse.
2. All AF patients in whom a rate-control or rhythm-control strategy is initiated to have their involvement in choosing a treatment strategy recorded.	Postoperative or haemodynamically unstable patients, or those otherwise not able to engage in a decision-making process.	Percentage of patient records with a record of involvement of the patient in the decision-making process.
3. All patients who are prescribed digoxin as initial monotherapy for rate control to have the reason for this prescription recorded where it is not obvious (eg sedentary patient, presence of contraindication to alternative agents).	None.	Percentage of patient records with a prescription of digoxin for initial rate-control monotherapy where the reason for digoxin prescription is: • sedentary patient • presence of contra-indications to beta-blockers or rate-limiting calcium antagonists • other reasons.
4 and 5. All patients should be assessed for risk of stroke/ thromboembolism and given thromboprophylaxis according to the stroke risk stratification algorithm (see Figure 11.1) and have this assessment and any antithrombotic therapy recorded.	Haemodynamically unstable patients or those in whom assessment is impossible or inappropriate.	Percentage of patient records with a record of risk assessment and thromboprophylaxis consistent with the stroke risk stratification algorithm.

Note: numbers correspond to the numbered list of key priorities for implementation.

3.5 Areas for future research

The GDG has identified the following five questions as key areas for further research:

▷ Cardioversion

Although cardioversion is a core treatment for many patients with AF, there is little evidence that compares the different modes (electrical and pharmacological), particularly in terms of cost effectiveness. Further, the studies that have considered the efficacy of preloading with antiarrhythmic drugs prior to electrical cardioversion have not reported long-term efficacy in maintaining sinus rhythm, or the cost effectiveness of this strategy.

- In patients scheduled for elective cardioversion what is the optimal form of cardioversion, in terms of the pre-cardioversion use of antiarrhythmic drugs, the mode of cardioversion (electrical or pharmacological), the cost effectiveness of each procedure and the impact on quality of life?

▷ Echocardiography

Echocardiography allows cardiac abnormalities such as left ventricular impairment to be diagnosed earlier than would be possible from signs and symptoms alone. However, no study has addressed the issue of whether performing routine echocardiography on all newly diagnosed AF patients would be more cost effective in diagnosing and treating heart disease earlier, than performing echocardiography only on those patients in whom there is a clinical suspicion of undiagnosed heart disease.

- What is the cost effectiveness of performing a routine echocardiographic examination in all newly diagnosed AF patients, compared to only selective examination based on clinical criteria?

▷ Anticoagulation with antiplatelet therapy

In the general AF population, the evidence suggests that combined therapeutic anticoagulation with antiplatelet therapy does not reduce the incidence of stroke or thromboembolism compared with therapeutic anticoagulation alone, and it may increase the incidence of bleeding. However, it is unclear whether there are certain subgroups of patients with AF for whom the therapeutic effects of combination therapy may be greater than either monotherapy. In particular, it is unclear whether combination therapy is justified in those AF patients who have stent implantation or a history of myocardial infarction (MI).

- Is there any additional benefit, in terms of overall vascular events, from combined anticoagulation with antiplatelet therapy for any subgroups of patients with AF such as those with prior MI or stent implantation?

▷ Pill-in-the-pocket treatment

Some patients with paroxysmal AF may have paroxysms infrequently. In these patients, the continuous use of antiarrhythmic drugs to suppress paroxysms may not be justified relative to their toxicity. No study has been undertaken in such patients in a UK population to determine whether a pill-in-the-pocket treatment strategy would be clinically or cost effective

compared with either the emergency department administration of treatment or continuous antiarrhythmic drug therapy.

- What is the clinical and cost effectiveness of pill-in-the-pocket treatment for those with paroxysmal AF compared with hospital-based administration or continuous antiarrhythmic therapy?

▷ Anticoagulation in paroxysmal AF

The frequency of paroxysms in patients with paroxysmal AF varies widely between patients. It remains unclear, however, whether the risk of stroke or thromboembolism varies between those with only infrequent paroxysms and those with more frequent paroxysms. It is also unclear whether, if the risk of stroke or thromboembolism is reduced in those with infrequent paroxysms, the use of anticoagulation is justified in such a low-risk group.

- What is the optimal anticoagulation strategy for those patients with paroxysmal AF who have infrequent paroxysms, and those who have more frequent paroxysms?

THE GUIDELINE

4 Identification and diagnosis

4.1 Presenting symptoms/pulse palpitation

AF can present in the setting of a wide variety of cardiac and non-cardiac conditions, it is often asymptomatic and can present with vague non-specific symptoms. Too often, AF is only detected after the patient presents with serious complications of AF, such as a stroke, thromboembolism or heart failure. The initial diagnosis of AF depends on associating symptoms such as breathlessness, dyspnoea, palpitations, syncope/dizziness or chest discomfort with AF.

Most of the data on presentation of AF patients have been based on white Caucasian populations, and limited data are available in relation to ethnicity and AF.[18] Furthermore, there may be important differences between hospital-based cohorts compared with community or population-based studies, as many do not present to hospital care, and if they do, it is often in the context of associated comorbidity such as ischaemic heart disease or heart failure. Indeed, many patients with AF in general practice remain asymptomatic. However, as AF commonly occurs in association with risk factors, such as hypertension, diabetes and ischaemic heart disease, opportunistic assessment of such patients for the presence of AF may be prudent, especially since such patients are frequently seen for check-ups in primary care.

While general population screening is beyond the scope of this guideline, targeted/opportunistic screening of symptomatic patients or those with risk factors may allow identification of AF patients. One recent study[19,20] aims to determine the baseline prevalence and the incidence of AF based on a variety of screening strategies and in doing so to evaluate the incremental cost effectiveness of different screening strategies, including targeted or whole population screening, compared with routine clinical practice, for detection of AF in people aged 65 and over. This study[20] – whose publication date fell outside of the date limits of the systematic literature search – reported that the baseline prevalence of AF in subjects older than 65 was 7.2%, with a higher prevalence in men (7.8%) and among patients aged 75 or older (10.3%), and indicated that the only strategy that improved on routine practice was opportunistic screening.

4.1.1 Methodological introduction

The results of nine studies are included in this report. Seven studies were critically appraised.[7,8,21–25] Of these, none reported the frequency of presenting symptoms in primary care in a UK (or other) population. Patients presenting to secondary care generally present with more severe symptoms. The studies:

- did not use a consistent terminology to classify AF symptoms. 'Dizziness' was also referred to as 'near syncope'[21] and 'chest pain' was also referred to as 'chest discomfort'[22]
- were single-centre studies
- had a variable proportion of patients presenting with *de novo* AF versus those with a previous history of AF.

Three of the appraised studies were not based on UK populations.[21–23] One study[8] reported the frequency of presenting symptoms between ethnic groups (white, Asian and black groups) but the numbers were too small to perform statistical comparisons.

4.1.2 Evidence statements

Dyspnoea, chest pain and palpitations were found to be the most common presenting symptoms in emergency admissions with newly diagnosed or previously diagnosed AF in the UK[7,8] or USA.[26–28]

Table 4.1 Presenting symptoms associated with emergency AF admissions

Study	N	Dyspnoea %	Chest pain %	Palpitations %	Dizziness /syncope %
Zarifis et al[8]	245	47.1	19.9	16.2	16.2
Lip et al[7]	170	51.8	34.1	25.9	18.8
Michael et al[26]	289	7	10	78	3
Burton et al[27]	266	12	24	40	9

Similar results were found in patients with chronic[23] (more than 7 days since onset of symptoms) and lone AF.[21]

In one study[24] (N=756) dyspnoea was the most commonly reported symptom in chronic and recent-onset AF (46.8%); palpitations were the most commonly reported symptom in paroxysmal AF (79.0%).[28]

Table 4.2 Presenting symptoms between paroxysmal, chronic and recent-onset AF patients

Symptom	Total	Paroxysmal	Chronic	Recent-onset
Palpitations (%)	54.1	79	44.7	51.5
Chest pain (%)	10.1	13.2	8.2	11
Dyspnoea (%)	44.4	22.8	46.8	58
Syncope/dizziness (%)	10.4	17.4	8	9.5
Fatigue (%)	14.3	12.6	13.1	18
Other (%)	0.9	0	1.8	0
None (%)	11.4	5.4	16.2	7

In two studies, stroke was reported as a presenting symptom of AF at rates of 5.1% and 3.2% respectively[22,25] and occurred at a rate of 12.7% in a study population combining both new-onset and previously diagnosed AF.[8,28]

4.1.3 From evidence to recommendations

Those with undiagnosed AF can receive treatment sooner if an opportunistic case finding is undertaken using manual pulse palpation in those presenting with symptoms commonly associated with AF. It was therefore considered good practice to check the blood pressure and pulse (manually) in all patients who present with breathlessness, dyspnoea, palpitations, syncope/dizziness or chest discomfort.

Many patients presenting with stroke are also found to be in AF, indicating a missed opportunity to diagnose the pre-existing AF and administer appropriate antithrombotic therapy.

RECOMMENDATION

R1 In patients presenting with any of the following:

- breathlessness/dyspnoea
- palpitations
- syncope/dizziness
- chest discomfort
- stroke/TIA

manual pulse palpation should be performed to assess for the presence of an irregular pulse that may indicate underlying AF. **C**

4.2 Electrocardiography

As with many chronic disorders, AF may be symptomatic or asymptomatic, and episodes of either can occur in the same patient.

Most symptomatic patients with AF present with symptoms related to the arrhythmia. However, such patients can have a wide variety of other cardio-respiratory presenting symptoms and clinical features[7,24] (see section 4.1).

Many patients with AF are asymptomatic and are picked up in general practice. One study[2] found that a third of AF patients had not had hospital contact for symptoms related to AF. Asymptomatic AF can be discovered incidentally during clinical examination by cardiac auscultation, 12-lead ECG recording, or 24-hour Holter recording that may have been performed for unrelated reasons.

The patient may also have presented with associated medical problems, such as heart failure, stroke or thromboembolism, and coincidental AF is detected. The duration of AF may be unknown in such patients, and whether AF was the cause or effect of the acute problem (eg stroke or heart failure) may be uncertain.

Many patients with risk factors for developing AF, such as hypertension and diabetes, do attend regular checkups with their GPs. In these cases then, there is the possibility of opportunistic case finding.

4.2.1 Methodological introduction

The two studies performed in UK primary care[29,30] evaluated the finding of an irregular pulse as a screening test for AF. Both studies included populations of over 65-year-olds and confirmed the diagnosis of AF by ECG.

4.2.2 Evidence statements

In one study,[29] the diagnostic accuracy of pulse palpation was compared between different age and gender groups in a primary care population aged 65 or over, and is summarised in Table 4.3. (II)

Table 4.3 Diagnostic accuracy of pulse palpitation between different age and gender groups

	Women 75+	Women 65–74	Men 75+	Men 65–74
Sensitivity	93 (66 to 100)	100 (16 to 100)	95 (75 to 100)	100 (54 to 100)
Specificity	71 (66 to 77)	86 (81 to 91)	71 (65 to 77)	79 (74 to 84)
PPV	14 (7 to 22)	8 (1 to 25)	23 (14 to 34)	12 (4 to 23)
NPV	99 (97 to 100)	100 (98 to 100)	99 (96 to 100)	100 (98 to 100)

All values are percentages with 95% confidence intervals.

One study[30] measured the diagnostic accuracy of three different methods of nurse-based screening for AF based on the presence of either continuous or intermittent pulse irregularities over a minimum of 20 seconds in a population aged over 65. The results are as shown in Table 4.4. (II)

Table 4.4 Comparison of the diagnostic accuracy of three different methods of pulse palpation to screen for the presence of AF

	Method 1	Method 2	Method 3
Sensitivity	91 (82 to 97)	72 (59 to 82)	54 (41 to 66)
Specificity	74 (72 to 77)	94 (93 to 96)	98 (97 to 99)
PPV	19 (15 to 23)	44 (35 to 54)	61 (47 to 73)
NPV	99 (98 to 100)	98 (97 to 99)	97 (96 to 98)

All values are percentages with 95% confidence intervals. Method 1: diagnostic accuracy based on the detection of any pulse irregularity; method 2: diagnostic accuracy based on the detection of frequent or continuous irregularities; method 3: diagnostic accuracy based on the detection of only continuous irregularities.

4.2.3 From evidence to recommendations

An irregular pulse was found to be sensitive to the presence of AF.[29] The positive predictive value was greater in those over 75 years old, as the prevalence of AF is known to be higher in this population. The negative predictive value of a regular pulse (>96%) was also emphasised. The results of a second study[30] suggested it would be prudent to consider any pulse irregularity as requiring further investigation to determine whether AF is present.

One study[19,20] whose publication date fell outside of the date limits of the systematic literature search confirmed the above results in an elderly UK population (over 65 years old). The study also showed that opportunistic case-detection for AF is a more cost-effective strategy than systematic screening and is associated with fewer ischaemic strokes and a greater proportion of diagnosed AF cases.

The evidence did not consider clinical indicators other than an irregular pulse and it was agreed that where there were other clinical indicators suggestive of AF, an ECG should still be performed. Nonetheless, the majority of patients presenting with AF will have an irregular pulse that may occur in the absence of any symptoms, and it is unlikely that AF will be present if the pulse is normal.

The diagnosis of AF does not require a 12-lead ECG recording. In the case of atrial flutter, however, a 12-lead ECG may be necessary, and may also occur in the presence of a regular pulse. The recommendation made below therefore applies only to AF case detection.

RECOMMENDATION

R2 An electrocardiogram (ECG) should be performed in all patients, whether symptomatic or not, in whom AF is suspected because an irregular pulse has been detected. **B(DS)**

4.3 Ambulatory ECG recording

Many patients with intermittent AF have asymptomatic paroxysms. In one study[31] it was estimated that only 1 in 12 paroxysms are symptomatic. Nonetheless, these patients remain at risk of complications associated with AF.

In patients with daily paroxysms, clinical practice is to perform a 24-hour Holter monitor, but this is less useful in patients who get paroxysms at intervals of more than 24 hours. In the latter category of patients, event ECGs (including transtelephonic monitors ('cardiomemos') and some implanted systems) are commonly used to detect/diagnose AF.

4.3.1 Methodological introduction

Ambulatory-ECG was defined as any electrocardiographic recording device that continuously recorded cardiac electrical activity while the patient was able to move around relatively freely without hindrance. Ambulatory-ECG included both Holter-monitoring and implanted recorders such as programmed pacemakers that generated a continuous ECG recording.

Event-ECG was defined as any electrocardiographic recording device which recorded only particular events, identified either automatically by a software program to detect arrhythmic episodes or by the onset of symptoms (when the patient manually switches on the device for the duration of the symptomatic episode), or a combination of the two. As with ambulatory-ECGs, event-ECGs record cardiac electrical activity while the patient is able to move around relatively freely without hindrance.

Studies were included if the sample population was reported to be patients with either suspected AF or suspected atrial arrhythmia. No studies compared the diagnostic accuracy of event-ECG devices with ambulatory-ECG devices over the same duration.

4.3.2 Evidence statements

One cross-over study[32] of patients suspected of atrial arrhythmia based on palpitations compared a patient-triggered event recorder over a mean period of 70 hours with a 48-hour Holter monitor. The event recorder detected proportionately more symptomatic episodes than the Holter monitor (67% of recorded episodes associated with symptoms versus 35% respectively; $p<0.001$) **(1b)**. Similarly, the event recorder yielded more arrhythmia diagnoses (19% versus 0% respectively; $p<0.005$). **(1b)**

In one study[33] which compared 24-hour Holter monitoring with automatic and patient triggered event recording (each over 30 days), the automatically-triggered event recorder had a higher diagnostic yield than the patient-triggered event recorder, which in turn had a higher diagnostic yield for diagnoses of AF than the Holter monitor (24%, 13% and 5% respectively). The automatically triggered event recorder was also more effective than the patient-triggered event recorder in detecting asymptomatic episodes of AF (52 events versus 1 event respectively).[34]

In one study[35] of 139 patients admitted with symptoms of acute stroke or transient ischaemic attack (TIA) who were ECG-negative for AF/flutter, seven (5%) were picked up in a second round of monitoring using a 24-hour Holter monitor. A further five (6%) patients were diagnosed with AF/flutter in a third round of monitoring using a 7-day event recorder (with both patient and automated triggering).[34]

4.3.3 From evidence to recommendations

No studies were found to compare the positive diagnostic yield per unit time between an ambulatory-ECG diagnostic tool and an event-ECG tool where the recordings were interpreted in a comparable manner.

One study[35] found that the use of event-ECG detected cases of AF remained undetected by both non-ambulatory and ambulatory-ECG. In addition, the study found that the use of ambulatory-ECG detected cases of AF remained undetected by non-ambulatory-ECG.

Also, a strategy of event-ECG diagnosis detected more symptomatic episodes and more positive diagnoses of atrial arrhythmias, including AF, than the strategy of ambulatory-ECG diagnosis.

RECOMMENDATION

R3 In patients with suspected paroxysmal AF undetected by standard ECG recording:

- a 24-hour ambulatory ECG monitor should be used in those with suspected asymptomatic episodes or symptomatic episodes less than 24 hours apart
- an event recorder ECG should be used in those with symptomatic episodes more than 24 hours apart. **B(DS)**

4.4 Echocardiography

Although most cardiologists will perform a transthoracic echocardiogram (TTE) on patients with AF referred to cardiology clinics,[36] echocardiography is not undertaken on all patients seen in primary or non-specialist secondary care.[2,7,8,37]

Regarding the use of echocardiography to identify stroke risk factors, although most stroke risk stratification criteria (see Appendix A) lay emphasis on clinical risk factors, there is a perception that TTE is mandatory to decide on antithrombotic therapy. In one study[38] echocardiography revealed cardiac abnormalities in many AF patients, although most had other clinical risk factors for thromboembolism and often echocardiography did not alter the management decision.

In clinical practice echocardiography has also been used to assess the risk of recurrent AF post cardioversion, as well as to assess the risk of developing postoperative AF. Finally, transoesophageal echocardiography (TOE) has been used to guide cardioversion (TOE-guided cardioversion (see section 5.4)), but this is a specialist investigation. TOE can also be used by specialists to assess the risk of stroke and thromboembolism.[39]

4.4.1 Methodological introduction

The results of 29 studies were included in this report. Studies were considered for inclusion if echocardiographic (TTE or TOE) variables were stratified into normal and abnormal ranges and tested, alongside clinical variables, as independent risk factors for clinically defined outcomes.

The clinical outcomes considered were:

- AF pathophysiology
- the recurrence of AF following successful cardioversion
- stroke or thromboembolism
- vascular death.

The presence of intracardiac thrombus was not considered as an echocardiographic measure of structural or functional heart disease. Rather, it was considered as a consequence of the disease.

4.4.2 Evidence statements

▷ AF pathophysiology

One study[40] found a left atrial diameter greater than 50 mm to be the only significant independent echocardiographic predictor for the development of a greater AF burden, in terms of the amount of time spent in AF or the frequency of AF episodes ($p<0.05$). (2++)

One study[41] found that in patients developing AF, it is more likely to lead to haemodynamic instability in patients with an atrial filling fraction less than 40% (RR 2.7; p<0.0001), or left-ventricular dysfunction (p<0.03) during sinus rhythm. (2+)

▷ Post-cardioversion recurrence

Left atrial haemodynamic dysfunction, as measured by a left atrial appendage velocity (LAA-V) greater than 40 cm/sec, has been found to be a significant independent predictor of maintained sinus rhythm following cardioversion in one study[42] (OR 5.2, 95% CI 2.7 to 10; p<0.0001). In another study,[43] a ratio of left atrial appendage area (LAA-V) over the left atrial area (LA area) greater than 0.009 was found to be an independent predictor of maintained sinus rhythm (OR 6.4; 95% CI 1.9 to 2.4; p=0.004). (2+)

Left atrial haemodynamic dysfunction, as measured by the presence of spontaneous echo contrast (SEC) in the left atrium, has not been found to be an independent predictor of sinus rhythm maintenance following cardioversion.[42,44] (2++)

Based on the results of four studies,[42,45–47] left atrial diameter is not an independent predictor of sinus rhythm maintenance following cardioversion (2+). However, two studies[44,48] did find a left atrial diameter of less than 45 mm (p=0.02) or less than 41 mm (p=0.008) to be an independent predictor. (2++)

One study,[45] while not finding left atrial diameter to be an independent predictor of sinus rhythm maintenance following cardioversion, did find a right atrial diameter of less than 37 mm to be an independent predictor (OR 5.9; 95% CI 1.4 to 25; p<0.02). (2+)

The presence of moderate or severe heart failure (NYHA>1) has been found to be an independent predictor of AF recurrence following cardioversion in one study[49] (p<0.0005) (2++). Another study,[46] found no such relationship between left ventricular dysfunction, when measured as either left ventricular end diastolic diameter (LVEDD) or left ventricular end systolic diameter (LVESD), and sinus rhythm maintenance. (2+)

One study[42] did not find the presence of mitral regurgitation to be an independent predictor AF recurrence following cardioversion (2+). Another study[50] found the presence of mitral annular abnormalities to be able to effectively predict the recurrence of AF at 12 months following cardioversion (positive predictive value (PPV) 79%, negative predictive value (NPV) 85%). (2+)

▷ Stroke or thromboembolism

Two studies[51,52] did not find aortic stenosis to be an independent predictor of stroke or thromboembolism. (2+)

One study[53] found the presence of complex aortic plaque to be an independent predictor of stroke in those over 70 years (OR 4.0, 95% CI 1.1 to 14; p=0.03). The same study did not find the same result in those under 70. (2++)

Based on the results of four studies,[51,53–55] it is unclear whether left atrial haemodynamic dysfunction, as measured by the presence of SEC, is an independent predictor of stroke or thromboembolism. (2++)

Based on the results of two studies,[55,56] left atrial haemodynamic dysfunction, as measured by LAA-V less than 20 cm/sec, is an independent predictor of stroke or thromboembolism (2+). Another study[53] found a similar result in those under 70 years, but not in those over 70 years. (2++)

Based on the results of six studies,[52,54,57–60] it is unclear whether an enlarged left atrium, measured either in terms of area or diameter, is an independent predictor of stroke or thromboembolism. (2+)

Based on the results of three studies,[57,61,62] (echocardiographically detected) left ventricular dysfunction is an independent predictor of stroke or thromboembolism: (2++)

- RR = 2.5 (1.5 to 4.4), p<0.001[61]
- RR = 2.6 (1.4 to 4.9), p=0.003[57]
- OR = 1.8 (1.2 to 2.7), p=0.003.[62]

Two other studies[51,54] did not find left ventricular dysfunction to be an independent predictor. (2+)

Based on the results of two studies,[52,62] left ventricular hypertrophy is an independent predictor of stroke or thromboembolism: (2+)

- OR = 2.8 (1.8 to 4.4), p=0.0001[62]
- OR = 6.56, p<0.01.[52]

Another study[51] did not find left ventricular hypertrophy to be an independent predictor. (2+)

Two studies[51,52] did not find mitral annular calcification to be an independent predictor of stroke or thromboembolism. (2+)

A meta-analysis of three clinical trials[61] (N=1,066) failed to find either mitral valve prolapse or regurgitation (of any degree) to be independent predictors of stroke or thromboembolism (2++). However, the results of a smaller study (N=290)[59] suggested that moderate-to-severe mitral regurgitation may be an independent negative predictor of stroke (OR 0.45, 95% CI 0.20 to 0.97) in a population at a low risk of stroke. (2++)

▷ Vascular death

One study[63] found that left-atrial haemodynamic dysfunction, as indicated by spontaneous echo contrast, was an independent predictor of vascular death in patients with AF, defined as either fatal non-haemorrhagic stroke, MI, congestive heart failure (CHF), systemic embolism or sudden cardiac death syndrome (RR 7.96, 95% CI 1.6 to 41; p=0.013) (2++). The study did not find the presence of structural, valvular or aortic cardiovascular disease to be independent predictors. (2++)

4.4.3 From evidence to recommendations

Echocardiography is able to identify factors that are independently predictive of successfully maintaining sinus rhythm following cardioversion. In particular, LAA-V measured by TOE is able to independently predict the successful maintenance of sinus rhythm following cardioversion.[42,43] TOE may therefore be used, in addition to other clinical variables, in determining the appropriateness of pursuing a rhythm-control strategy involving cardioversion.

In most cases risk stratification for stroke or thromboembolism and the decision to administer appropriate thromboprophylaxis can be made on purely clinical (non-echocardiographic) characteristics. However, the stroke risk may be unclear in some patients, in which case echocardiography may be useful in refining the risk. In particular, TOE may be used to identify the presence of complex aortic plaque[53] and impaired left atrial haemodynamics.[53,55,56] TTE may be used to identify left ventricular dysfunction or hypertrophy,[57,61,62] that may not be associated with overt heart failure.[52,62]

In many patients with AF, there may be indications other than the AF itself that make it necessary to perform an echocardiographic examination. For example, it may be used to identify suspected co-present heart disease. TOE may further be used to detect cardiac abnormalities not identified through TTE (eg patent foramen ovale).

The recommendations made here are specifically for those instances where echocardiography is used in relation to AF and how the results may influence the choice of treatment strategy or antiarrhythmic drug.

RECOMMENDATIONS

R4 Transthoracic echocardiography (TTE) should be performed in patients with AF:

- for whom a baseline echocardiogram is important for long-term management, such as younger patients **D(GPP)**
- for whom a rhythm-control strategy that includes cardioversion (electrical or pharmacological) is being considered **C**
- in whom there is a high risk or a suspicion of underlying structural/functional heart disease (such as heart failure or heart murmur) that influences their subsequent management (for example, choice of antiarrhythmic drug) **D(GPP)**
- in whom refinement of clinical risk stratification for antithrombotic therapy is needed (see section 11.6). **C**

R5 TTE should not be routinely performed solely for the purpose of further stroke risk stratification in patients with AF for whom the need to initiate anticoagulation therapy has already been agreed on appropriate clinical criteria (see section 11.6). **D(GPP)**

R6 Transoesophageal echocardiography (TOE) should be performed in patients with AF:

- when TTE demonstrates an abnormality (such as valvular heart disease) that warrants further specific assessment **D(GPP)**
- in whom TTE is technically difficult and/or of questionable quality and where there is a need to exclude cardiac abnormalities **D(GPP)**
- for whom TOE-guided cardioversion is being considered. **D(GPP)**

5 Cardioversion

5.1 Electrical versus pharmacological cardioversion

Cardioversion is performed as part of a rhythm-control treatment strategy, and if successful restores sinus rhythm.[64] However, not all attempts at cardioversion are successful, and at one year post cardioversion approximately 50% of patients are back in AF.[65]

There are two types of cardioversion: electrical (ECV) and pharmacological (PCV). The optimal techniques and recommended protocols for performing cardioversion have been widely discussed in the literature.[64,66–68] PCV involves the use of various antiarrhythmic drugs, some of which may also be used to maintain sinus rhythm after electrical cardioversion (see section 6.1) or concomitantly with ECV (see section 5.3). Current clinical practice regards PCV as the preferred strategy in patients presenting with AF of recent onset (within 48 hours); ECV is regarded as the preferred strategy where the AF is more prolonged. Cardioversion is not normally attempted until possible underlying precipitants (eg thyrotoxicosis, infections) have been successfully treated and any electrolyte abnormalities corrected.

In clinical practice, young patients who develop AF but have no underlying structural heart disease often have an acute identifiable precipitant for their AF (eg alcohol). These cases often revert spontaneously to sinus rhythm without the need to attempt cardioversion (ECV or PCV).

5.1.1 Methodological introduction

Two studies were used to measure the success and failure rates of cardioversion but neither used double blinding and they may have been subject to expectation bias or confounding. Both studies had short follow-up periods, and therefore the incidence of thromboembolism or longer-term adverse events were not reliably measured. Neither study considered outcome measures such as exercise capacity or overall quality of life. There were conflicting results for the outcome measure 'duration of hospital stay', so no reliable conclusions could be drawn regarding health economic outcome measures.

5.1.2 Evidence statements

No difference has been found in rates of successful cardioversion between ECV and PCV as the initial treatment strategy (73% versus 74% respectively,[69] and 77% versus 81% respectively[70]). (1+)

Patients who had PCV as the initial treatment option, followed by ECV if sinus rhythm was not restored, were more likely to be cardioverted than those patients in whom the treatment preference was reversed (96% versus 84% respectively; $p<0.05$)[69] (1+). Similar results were observed for a subgroup of patients with lone AF (100% versus 77% $p<0.01$) although no significant differences have been found for those with either chronic or recent-onset AF or those with structural heart disease.[69] (1+)

Initiating treatment with PCV cost less per successful cardioversion than initiating treatment with ECV in all patients (US$1,240 versus US$1,917 p=0.002).[69] Initial PCV also cost less per successful cardioversion in patients with lone AF (US$965 versus US$2,021), and in patients with structural heart disease (US$1,223 versus US$1,814). Mean cost per patient was US$1,188 in the initial PCV and US$1,603 in the initial ECV group. The increased cost of ECV was attributed to heart monitoring, medications and oxygen.

5.1.3 From evidence to recommendations

Few studies set out to compare which patients would benefit most from ECV versus PCV. Two studies[69,70] failed to find any difference between these strategies when used as the initial treatment option. Concern was expressed regarding the overall applicability of the results of one study[70] to UK clinical practice. The health economics data supported the clinical outcomes that using PCV as first-line treatment followed by ECV if PCV failed was the most cost effective. The health economic study costings were based on US dollars.

The evidence failed to address many issues (eg incidence of thromboembolism and stroke, and improvements to quality of life). The choice of strategy was considered to be dependent on local facilities and available expertise. It was recognised that some clinicians perform elective cardioversion under general anaesthesia, while others performed the procedure under sedation. Also, there has been a move towards nurse-led cardioversion services.[71–73]

As the treatments were considered equally effective, highlighting patient choice was important. Informing patients that neither treatment has been shown to be more effective than the other is important and can help to prevent patients becoming disillusioned when cardioversion fails.

It was concluded that the available evidence suggested pharmacological and electrical cardioversion to be of comparable efficacy in recent onset AF. However, it was felt that in more prolonged cases of AF electrical cardioversion is the preferred option based on clinical experience and current clinical practice. It was also felt preferable to attempt cardioversion as soon as possible following AF onset to maximise the likelihood of a successful outcome.

RECOMMENDATION

R7 In patients with AF without haemodynamic instability for whom cardioversion is indicated:

- the advantages and disadvantages of both pharmacological and electrical cardioversion should be discussed with patients before initiating treatment **D(GPP)**
- where AF onset was within 48 hours previously, either pharmacological or electrical cardioversion should be performed **B**
- for those with more prolonged AF (onset more than 48 hours previously) electrical cardioversion should be the preferred initial treatment option. **D(GPP)**

5.2 Pharmacological cardioversion

Clinical practice commonly uses Vaughan-Williams Class Ia, Ic and III antiarrhythmic drugs for PCV.[68] However, these agents are associated with a risk of proarrhythmia in the presence of electrolyte abnormalities and ischaemic or structural heart disease.[74–76] This risk should be considered when choosing drugs for individual patients. The fast-acting intravenous beta-blocker esmolol has also been used and shown to be effective.[77,78] Digoxin has been shown to be ineffective for use in PCV.[79–81]

Patients undergoing PCV are usually admitted to hospital and have the antiarrhythmic drug administered intravenously, under ECG monitoring. These drugs may also be administered orally, and have been shown to have comparable efficacy to intravenous administration at 24 hours.[82–85] On occasion, an oral antiarrhythmic agent may be prescribed for those patients with paroxysmal AF where the drug has previously been known to work effectively and safely, and there are no contraindications (see section 8.2).

In the UK, the most commonly used drugs for PCV in patients with persistent AF are amiodarone, flecainide, propafenone and sotalol. This section addresses the efficacy of amiodarone versus the other three drugs.

5.2.1 Methodological introduction

The results of 15 studies are reported; one was a meta-analysis,[86] and the remainder were RCTs.

The meta-analysis[86] compared the efficacy of amiodarone to the Class Ic agents flecainide or propafenone, but did not report the individual drug comparisons separately. The results of two studies[85,87] included in the meta-analysis were not reported separately, one[85] because a statistical comparison was not made between the study drugs, and the other[87] because the study was only available in Italian.

All of the studies considered the comparison between two intravenously or orally administered antiarrhythmic drugs. Studies comparing the oral administration of one drug with the intravenous administration of another were excluded on the basis that the route of administration could confound the results of drug efficacy.

Regarding the comparison between the two Class III agents, amiodarone and sotalol, only one study[88] compared intravenous amiodarone with intravenous sotalol, but with additional oral administration of each drug as required. Although not licensed in the UK, results involving the intravenous preparation of propafenone have been included in this report as conclusions may be extrapolated to flecainide (as an intravenous flecainide preparation is licensed in the UK), or to oral preparations of propafenone.

With one exception,[89] all of the studies were in patients with acute- or recent-onset AF (in all cases less than 2 weeks). However, in three studies[88,90,91] only patients with acute-onset of less than 24 or 48 hours were considered. All studies excluded patients with moderate-to-severe heart failure (New York Heart Association (NYHA) grade greater than II) or left ventricular dysfunction. All studies reported the restoration of sinus rhythm as primary outcome, rather than the frequency of side effects associated with each drug.

5.2.2 Evidence statements

▷ Amiodarone versus sotalol

One study[88] reported no significant difference in efficacy between an intravenous/oral combination of amiodarone and sotalol for the restoration of sinus rhythm in patients with AF or atrial flutter of less than a 24-hour duration (**1+**). A similar result was reported in another study[89] using only oral administration, where both drugs were administered prior to electrical cardioversion. (**1++**)

One study[88] reported no significant difference in the frequency of adverse side effects between amiodarone and sotalol for the cardioversion of acute-onset AF or atrial flutter (two instances of heart failure in the amiodarone-treated group – both of which occurred in patients with impaired left ventricular function (LVEF) <40% – versus two instances of hypotension in the sotalol-treated group). (**1+**)

▷ Amiodarone versus flecainide/propafenone

A meta-analysis[86] of seven primary studies comparing parenteral or oral formulations of amiodarone with either flecainide or propafenone, found flecainide/propafenone to be more effective than amiodarone in restoring sinus rhythm within the first 8 hours after administration, but not at 24 hours (see Table 5.1). (**1+**)

Table 5.1 Relative risk of remaining in AF with flecainide or propafenone compared with amiodarone over different time periods

Time (hours)	RR (95% CI)
2	0.35 (0.24 to 0.50)
5	0.44 (0.31 to 0.61)
8	0.57 (0.57 (sic.) to 0.80)
24	0.95 (0.83 to 1.09)

▷ Amiodarone versus flecainide

One study[90] (N=100) found intravenous flecainide to be more effective in terms of restoring sinus rhythm than intravenous amiodarone throughout the follow-up period of 12 hours, as well as in terms of the median time taken to restore sinus rhythm (**1+**). The results of another smaller study[92] did not find any significant difference throughout a follow-up period of 8 hours. (**1+**)

▷ Amiodarone versus propafenone

Three studies[90,91,93] found intravenous propafenone to be more effective and faster in restoring sinus rhythm than intravenous amiodarone for up to 8 hours following drug administration (**1+**). At 24 hours, the two drugs were comparable.[91,93] (**1+**)

One study[94] found no significant difference between propafenone and amiodarone in terms of restoring sinus rhythm when effectively administered as a single oral dose (with additional oral doses if sinus rhythm was not restored within 24 hours. (1+)

▷ Flecainide versus propafenone

Based on the results of four studies,[90,95–97] it is inconclusive whether intravenous flecainide is more effective than intravenous propafenone (see Table 5.2). (1+)

Table 5.2 Percentage of study participants reverting to sinus rhythm following administration of flecainide or propafenone

Study	N	Time (hours)	Flecainide	Propafenone	p
Martinez-Marcos et al[90]	100	1	58	60	NS
Kingma et al[97]	70	1	86	55	<0.002
Kondili et al[96]	40	1	50	25	NS
Martinez-Marcos et al[90]	100	8	82	68	NS
Martinez-Marcos et al[90]	100	12	90	72	0.022

Three studies[90,95,96] found no significant difference in the mean time taken to restore sinus rhythm between intravenous flecainide and intravenous propafenone. (1+)

Based on the results of two studies, propafenone and flecainide are comparable in their efficacy[85,98] and speed[85] in restoring sinus rhythm when administered orally. (1+)

5.2.3 From evidence to recommendations

The evidence relied heavily on one study[90] with a relatively small number of patients (N=100). The evidence suggested that Class Ic drugs (flecainide and propafenone) are more effective than amiodarone at cardioverting patients with recent-onset AF at 2, 5, and 8 hours after administration. However, at 24 hours the difference in efficacy disappears, indicating that amiodarone has a longer period of onset than the Class Ic drugs. This result is also consistent with all of the primary studies, with no study finding any significant difference in efficacy at 24 hours or longer periods of observation.

The results of one study[90] suggested that flecainide and propafenone are comparable in terms of the time taken to revert to sinus rhythm (ie cardioversion), although at 12 hours flecainide was associated with a greater likelihood of reversion to sinus rhythm than propafenone was. A separate, unblinded study[88] suggested that for use in pharmacological cardioversion amiodarone and sotalol were comparable to each other in terms of both efficacy and safety.

It was noted that the trials excluded patients with structural or functional heart disease (left ventricular dysfunction). There were concerns about the use of Class I and Class III anti-arrhythmic drugs in these patients, although amiodarone was considered to be safe. The evidence assessing the use of digoxin for PCV was excluded from the literature search as this was considered to be an inappropriate use of this drug.

RECOMMENDATION

R8 In patients with persistent AF, where the decision to perform pharmacological cardioversion using an intravenous antiarrhythmic agent has been made:

- in the absence of structural heart disease,* a Class 1c drug (such as flecainide or propafenone) should be the drug of choice **B**
- in the presence of structural heart disease,* amiodarone should be the drug of choice. **D(GPP)**

*Coronary artery disease or left ventricular dysfunction.

5.3 Electrical cardioversion with concomitant antiarrhythmic drugs

Electrical cardioversion (ECV) alone is not always successful in inducing or maintaining sinus rhythm. In some cases, there is complete failure of ECV ('complete shock failure' or 'no conversion'). In other cases, AF recurs within a few minutes after a short period of sinus rhythm (immediate recurrence), sometimes recurrence is delayed from 1 day to 2 weeks (subacute or early recurrence), and sometimes AF recurrence occurs beyond 2 weeks (late recurrence).[99]

It is estimated that complete shock failure and immediate recurrence occur in approximately 25% of patients undergoing ECV, and subacute/early recurrences occur within 2 weeks in another 25%.[99]

In clinical practice, patients who have had a failed ECV or PCV or a relapse to AF while maintained on antiarrhythmic drugs, often have a further attempt at cardioversion, normally using ECV.

It is perceived that the concomitant administration of antiarrhythmic drugs increases the likelihood of successful cardioversion and the maintenance of sinus rhythm post cardioversion; this section addresses the evidence for this.

5.3.1 Methodological introduction

All 11 studies were RCTs, comparing either an antiarrhythmic drug with placebo[100–104] or comparing two or more antiarrhythmic drugs.[105,105–110] The results focus on the efficacy of concomitant antiarrhythmic drugs in ECV as none of the studies had sufficient power to detect differences in side effects.

Many of the studies considered the administration of antiarrhythmic drugs in both the pre-cardioversion and post-cardioversion periods. It is also unclear in many studies whether adjunctive rate-control therapy, such as digoxin or beta-blockers, was being prescribed in addition to the antiarrhythmic drugs.

The studies were similar in terms of patient population, drug dosages and outcome measures. There was some variance in the classification of successful cardioversion, as well as the policy on the inclusion or exclusion of patients with spontaneous cardioversion occurring prior to elective cardioversion.

5.3.2 Evidence statements

▷ Restoration of sinus rhythm

Four studies[101,105–107] compared pre-cardioversion amiodarone to rate-control drugs or placebo in relation to the incidence of successful cardioversion (see Table 5.3).

Table 5.3 Comparison of amidarone with various controls in terms of the incidence of successful cardioversion

	Study	N	Control	Amiodarone (%)	Control (%)	p
(1+)	Villani et al[105]	74	Digoxin	91	67	<0.05
(1+)	Villani et al[105]	90	Diltiazem	91	76	<0.05
(1+)	Capucci et al[107]	61	Diltiazem	87	65	<0.05
(1++)	Channer et al[101]	161	Placebo	72	79	NS
(1+)	Jong et al[106]	77	Various*	87	58	<0.05

*Study used either verapamil or propranolol to control ventricular rate.

One study[89] found that, in terms of the proportion of patients in whom sinus rhythm was restored either spontaneously or through the administration of electrical cardioversion, amiodarone and sotalol had equal efficacy (p=0.98) when administered from 28 days prior to scheduled cardioversion (**1++**). The study also found that those receiving either amiodarone or sotalol in the 28-day period prior to scheduled cardioversion had a higher prevalence of sinus rhythm at the end of the period, either through spontaneous restoration of sinus rhythm or through the administration of electrical cardioversion (p=0.01). (**1++**)

Six studies[100,102–105,108] compared various other antiarrhythmic drugs pre-cardioversion to rate-control drugs or placebo in relation to successful cardioversion (see Table 5.4).

Table 5.4 Comparison of various antiarrhythmic drugs with various controls in terms of the incidence of successful cardioversion

	Test/control	N	Test (%)	Control (%)	p
(1+)	Diltiazem/digoxin[105]	76	67	76	NS
(1++)	Flecainide/placebo[100]	54	73	82	NS
(1+)	Procainamide/placebo[104]	100	83	78	NS
(1+)	Propafenone/placebo[102]	35	73	74	NS
(1+)	Propafenone/placebo[103]	100	84.4	82.4	NS
(1+)	Verapamil/digoxin[108]	100	67	89	<0.05

One study[100] found pre-cardioversion flecainide use resulted in more successful first shocks in comparison with placebo (65% versus 30%, respectively; p=0.04). (**1++**)

▷ Recurrence of AF

The administration of amiodarone throughout the pre- and post-cardioversion period is associated with a reduced rate of relapse to AF compared with placebo or other drugs with a primary chronotropic effect (see Table 5.5).

Table 5.5 Comparison of amiodarone with other drugs or placebo in terms of the incidence of late AF recurrence post cardioversion

	Study	N	Control	Period (months)	Amiodarone (%)	Control (%)	p
(1+)	Villani et al[105]	74	Digoxin	1	28	78	<0.01
(1+)	Villani et al[105]	90	Diltiazem	1	28	56	<0.01
(1+)	Capucci et al[107]	61	Diltiazem	2	31	52	<0.01
(1++)	Channer et al[101]	161	Placebo	2	34	80	<0.001
(1+)	Jong et al[106]	77	Various*	2	37	77	<0.05

*Verapamil or propranolol.

It is unclear whether the administration of antiarrhythmic drugs pre-cardioversion decreases the likelihood of AF recurrence either in the first 48 hours following successful cardioversion or at up to 12 weeks (see Table 5.6).

Table 5.6 Comparison of antiarrhythmic drugs with control drugs in terms of the incidence of early or late AF recurrence post cardioversion

	Test/Control	N	Period	Test (%)	Control (%)	p
(1+)	Amiodarone/diltiazem[107]	61	24 hours	5	10	NS
(1+)	Amiodarone/digoxin[105]	74	24 hours	3	12	<0.01
(1+)	Diltiazem/digoxin[105]	76	24 hours	12	2	<0.01
(1+)	Amiodarone/diltiazem[105]	90	24 hours	3	2	NS
(1+)	Propafenone/placebo[103]	100	48 hours	12.2	35.8	<0.05
(1++)	Flecainide/placebo[100]	54	4 weeks	55	52	NS
(1+)	Verapamil/digoxin[108]	100	8 weeks	84	63	0.03
(1+)	Verapamil/digoxin[108]	100	12 weeks	91	72	0.03

One study[109] found the addition of verapamil to propafenone to be more effective than propafenone alone in terms of the incidence of post-cardioversion AF recurrence at 1 week and 3 months (1+). Another study[110] found no significant difference in the incidence of post-cardioversion AF recurrence at 1 week or 1 month between verapamil in addition to amiodarone and amiodarone alone. (1+)

▷ Defibrillation energy

It is inconclusive whether the administration of antiarrhythmic drugs is associated with either a reduced mean amount of energy per successful shock[102,104,105] or the total amount of energy per successful cardioversion attempt.[100,101,103,106] (**1++**)

5.3.3 From evidence to recommendations

Amiodarone and sotalol generally increased the likelihood of a successful cardioversion in comparison with controls in trials.[89,105–107] The historical literature regarding the amount of energy delivered during ECV was not considered to reflect current practice. These studies administered a low energy level shock and then escalated to a higher energy level shock. Therefore it was unclear whether the administration of antiarrhythmic drugs decreased the energy requirement for successful cardioversion. Furthermore, biphasic defibrillators (which deliver lower energy shocks) are increasingly used.

The evidence was also confounded by:

- the same antiarrhythmic drugs either being administered following a successful cardioversion for the long-term maintenance of sinus rhythm,[111,112] or
- the use of pre-cardioversion loading of antiarrhythmics not being reported in trial protocols, or considered as a comparison in long-term follow-up studies of sinus rhythm maintenance.

Measuring the immediate recurrence of AF was of limited value compared with recurrences in the longer term. From the limited data available based on small patient numbers, there was support for the use of amiodarone, sotalol and, possibly, propafenone in reducing the incidence of AF recurrences post cardioversion.

None of the evidence reflected concerns regarding potential adverse effects of antiarrhythmic drugs such as amiodarone. It was therefore not considered appropriate to recommend its use for routine ECV, although it may be beneficial in cases with a perceived increased risk of unsuccessful electrical cardioversion (eg long duration of AF).

There was no evidence found to support the use of other antiarrthymic drugs. Further, the concomitant use of digoxin did not improve cardioversion success.

RECOMMENDATION

R9 When patients with AF are to undergo elective electrical cardioversion and there is cause for heightened concern about successfully restoring sinus rhythm (such as previous failure to cardiovert or early recurrence of AF), concomitant amiodarone or sotalol* should be given for at least 4 weeks before the cardioversion. **B**

*Sotalol to be progressively titrated from 80 mg twice daily up to 240 mg twice daily.

5.4 Transoesophageal echocardiography-guided cardioversion

Cardioversion of AF is associated with an increased risk of stroke and thromboembolism. In order to minimise this risk, anticoagulation is conventionally recommended for a minimum of 3 weeks before and during cardioversion, and for a minimum of 4 weeks after cardioversion. Even when pre-cardioversion transoesphageal echocardiography (TOE) fails to demonstrate left atrial thrombus, some patients have a thromboembolism post cardioversion (especially if no anticoagulation has been administered).[68,113]

As it may take some time to achieve therapeutic international normalised ratio for 3 consecutive weeks, some patients may wait months before cardioversion is attempted. As it is perceived that patients are more likely to successfully cardiovert the shorter the time they have been in AF, strategies to facilitate early cardioversion have been explored.

One strategy is TOE-guided cardioversion, where a patient with AF of more than 48 hours duration has a TOE to assess for intracardiac thrombus. In the absence of thrombus, heparin is usually given and cardioversion is performed. Anticoagulation with warfarin is subsequently continued for a minimum of 4 weeks. Patients in whom a thrombus is identified by TOE are considered at high risk of post-cardioversion thromboembolism and are usually treated with conventional therapeutic anticoagulation for at least 3 to 4 weeks before the TOE is repeated (see Figure 5.1). This strategy requires an experienced TOE operator, especially since visualisation of thrombus may be operator-dependent.

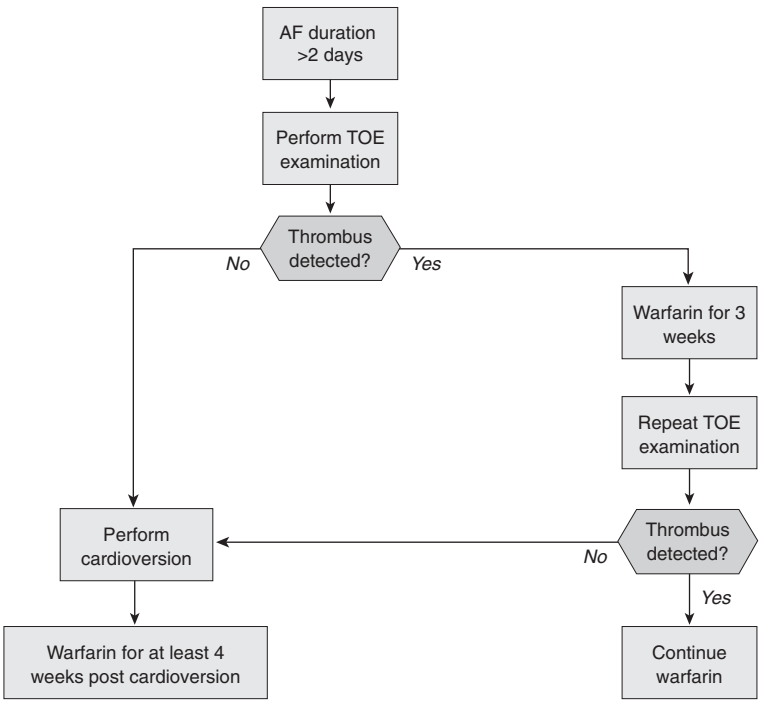

Figure 5.1 Cardioversion with TOE-guided strategy

5.4.1 Methodological introduction

Only studies where a comparison was made between a strategy of TOE-guided cardioversion and cardioversion without a prior TOE were included.

The primary clinical outcome of these studies was that the incidence of post-cardioversion thromboembolic events and other outcomes reported included the restoration and maintenance of sinus rhythm.

Of the two studies considering clinical outcomes included, one was a RCT,[114] and the other a cohort study.[115] In the former, in addition to the use of TOE examination, both the duration of anticoagulation and treatment were different between the two groups; in the later study, only the use of TOE examination was different between the two groups. Neither of the studies were adequately powered.

Of the two studies considering health economic outcomes,[116,117] one[117] estimated the cost per quality-adjusted life-year (QALY) of three strategies:

(1) conventional therapy transthoracic echocardiography (TTE) and warfarin therapy for one month before cardioversion)
(2) initial transthoracic echocardiography followed by transoesophageal echocardiographic-guided cardioversion and early cardioversion if no thrombus is detected (TTE/TOE)
(3) initial TOE-guided cardioversion with early cardioversion if no thrombus is detected.

The other study[116] estimated the costs and incremental cost per QALY of TOE-guided anticoagulation versus conventional anticoagulation based on the Assessment of Cardioversion Using Transoesophageal Echocardiography (ACUTE) trial.[114]

5.4.2 Evidence statements

One study[114] did not find any significant difference between TOE-guided cardioversion and a conventional strategy in terms of the incidence of thromboembolic events, stroke, successful initial cardioversion or maintenance of sinus rhythm at 8 weeks (**1+**). The difference in terms of mortality was of borderline significance (p=0.06) in favour of the conventional strategy. (**1+**)

A second study also failed to find any significant effect on the incidence of all embolic events between the two strategies.[115] (**2+**)

One study[114] found a lower incidence of bleeding events with a TOE-guided strategy compared with a conventional strategy (2.9% versus 5.5%, respectively; p=0.03). (**1+**)

TOE-guided cardioversion (US$ 2,774) costs less than TTE/TOE-guided cardioversion (US$3,070) and conventional strategy (US$3,106). Including the gains in QALYs, TOE-guided cardioversion is the least costly strategy with similar effectiveness (TOE accumulated 8.49 QALYs, TTE/TOE and conventional therapy both accumulated 8.48). The sensitivity analysis indicated that the results depend on a lower risk of cardioversion-related thromboembolism after negative TOE compared with conventional therapy.[117]

Overall, there was no significant difference in the mean costs per patient between TOE-guided and conventional care in the simulation model (US$3,503.09 versus US$3,423.52) and the hospital charge data from the ACUTE trial data (US$6,508 versus US$6,239, p=0.50). The analytic model indicated the initial treatment costs per patient were higher in the TOE group

(US$2,639.67 versus US$2,429.01), but outcome-associated costs were lower (US$863.42 versus US$994.51). The decision model indicated that the TOE-guided strategy costs US$185 more than conventional therapy when all treatment and outcome data are included (US$7,090 versus US$6,905). An incremental cost per QALY of TOE-guided cardioversion was calculated at US$15,455.[116]

5.4.3 From evidence to recommendations

Overall, the clinical studies suggest that TOE-guided cardioversion is of comparable efficacy to conventional strategy.[114,115] Although bleeding was reduced in the TOE-guided strategy, this was perceived to be a result of the shorter time spent on anticoagulation, and therefore TOE-guided cardioversion could be deemed preferable in patients with an increased bleeding risk. The health economic studies suggested that TOE-guided cardioversion may be a cost-effective treatment strategy.

The theoretical advantage of early cardioversion being more likely to be successful was not supported by the current clinical trial data. However, the studies were underpowered to detect significant differences in this, and in mortality and embolic event rates. TOE-guided cardioversion was considered a specialised procedure requiring appropriately experienced staff and appropriate facilities. However, it was considered that TOE-guided cardioversion should be an available treatment, as some patients would prefer the option of not being on prolonged anticoagulation.

RECOMMENDATION

R10 In patients with AF of greater than 48 hours duration, in whom elective cardioversion is indicated:

- both TOE-guided cardioversion and conventional cardioversion should be considered equally effective **B**
- a TOE-guided cardioversion strategy should be considered:
  - where experienced staff and appropriate facilities are available, and **D(GPP)**
  - where a minimal period of pre-cardioversion anticoagulation is indicated due to patient choice or bleeding risks. **C**

5.5 Cardioversion treatment algorithm

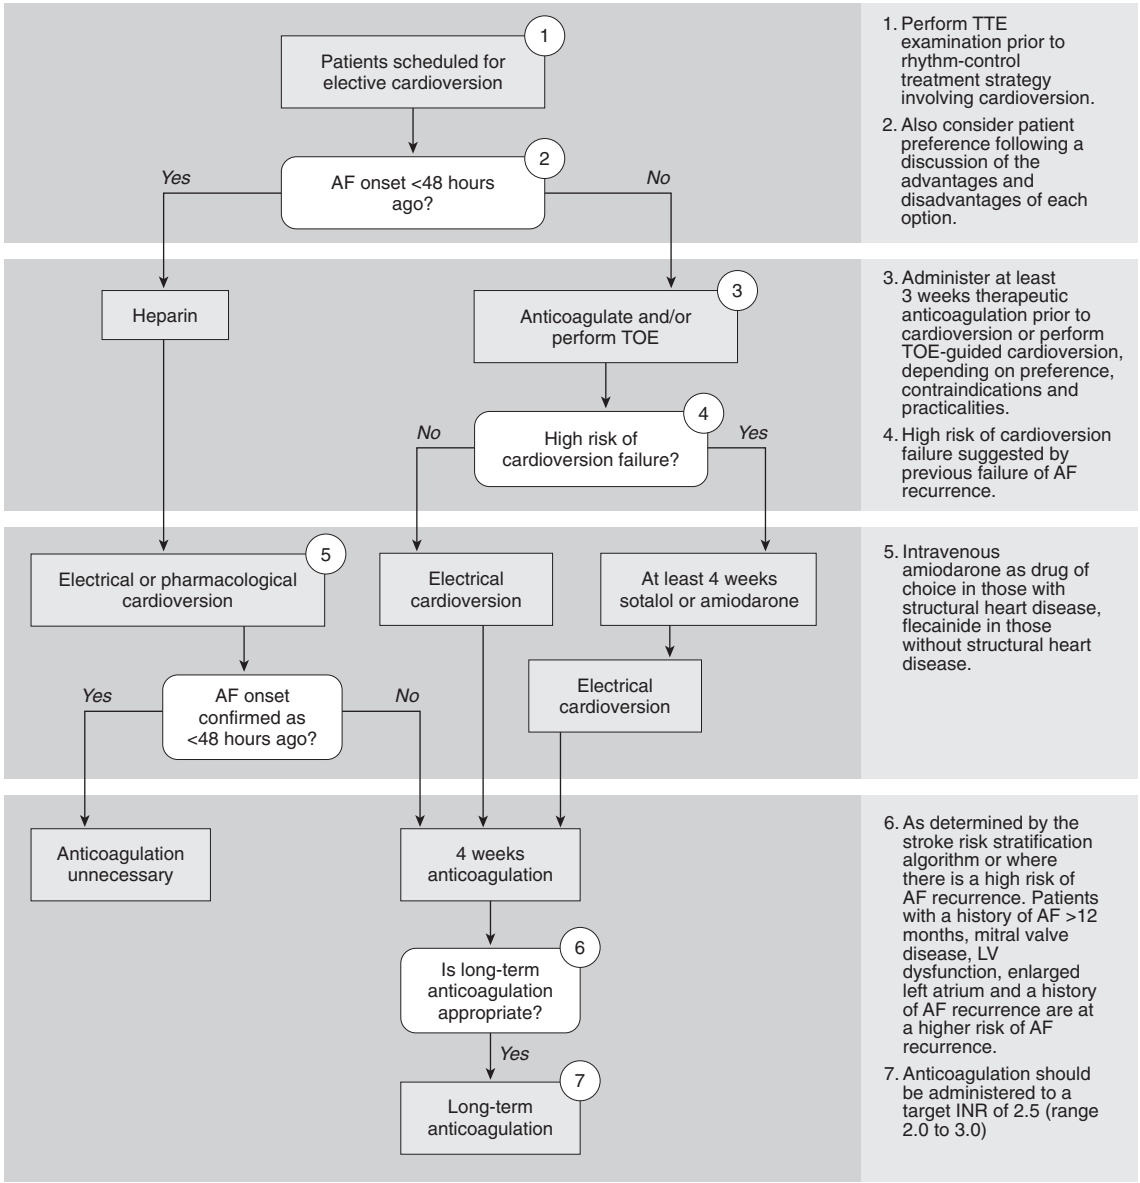

Figure 5.2 Cardioversion treatment algorithm

6 Treatment for persistent AF

6.1 Rate control versus rhythm control

AF is associated with increased mortality and morbidity. Currently, there are two main treatment strategies, rate control and rhythm control.

Rate control involves the use of chronotropic drugs or electrophysiological/surgical interventions to reduce the rapid heart rate (ventricular rate) often found in patients with AF. Although the atria continue to fibrillate with this strategy, it is nonetheless thought to be an effective treatment as it improves symptoms and reduces the risk of associated morbidity. However, the persistence of the arrhythmia continues the risk of stroke and thromboembolic events occurring. This risk is reduced by administering antithrombotic drugs (see section 7.2).

Rhythm control involves the use of electrical or pharmacological cardioversion or electrophysiological/surgical interventions to convert the arrhythmia associated with AF to normal sinus rhythm. Patients who have been successfully cardioverted are generally administered antiarrhythmic drugs for the long term to help prevent the recurrence of AF. The rhythm-control strategies also require the appropriate administration of antithrombotic therapy to reduce the risk of stroke and thromboembolic events occurring (see section 6.2).

There remain uncertainties about the most appropriate initial treatment strategy for individual patients. This section addresses which strategy is most suitable for which patient groups.

6.1.1 Methodological introduction

Five randomised controlled trials[118–122] were included in this evidence report, along with one pre-defined substudy[123] of one of the original trials. Each study compared rate-control strategies to rhythm-control strategies and involved the use of various drug therapies within each strategy.

In all rate-control treatment groups, concomitant antithrombotic therapy was administered, whereas in rhythm-control treatment groups it was administered to patients only when it was considered appropriate by the treating physician.

The follow-up periods and number of participants varied widely between the studies and only two studies[118,119] included participants who had undergone at least one previous attempt at electrical cardioversion.

None of the studies were double-blind, and in some the participants were able to swap between the different treatment groups. For example, upon multiple failed attempts at cardioversion, participants were treated according to rate-control protocols. An intention-to-treat analysis was employed in those studies where swapping was allowed.

One meta-analysis was also included.[124] Because the meta-analysis only considered the outcomes of mortality and ischaemic stroke, the results of the four primary studies will be reported for other outcomes.

Two studies[125,126] compared the cost effectiveness of the two strategies. One study[125] estimated the incremental cost per life-year gained in rhythm control versus rate control. The other study[126] estimated the cost per avoided endpoint (cardiovascular morbidity or mortality).

6.1.2 Evidence statements

For those older than 65 or those with coronary artery disease, a significant difference has been found in favour of rate control in terms of all-cause mortality.[121] (**1+**)

For those with heart failure (congested heart failure (CHF) or left ventricular ejection fraction (LVEF) <50%), the adoption of a rhythm-control strategy is associated with a lower incidence of all-cause mortality[121] (**1+**). Another study[123] reported that the overall incidence of adverse cardiovascular events in those with predominantly mild heart failure (NYHA II) was comparable between rate control and rhythm control. (**1+**)

Overall, a non-significant difference has been found in terms of all-cause mortality between rate and rhythm control[124] (13.0% versus 14.6%, p=0.09). (**1+**)

In patients with recurrent AF, a strategy of rhythm control was associated with a higher incidence of proarrhythmic events (torsades de pointes (0.8% with rhythm control versus 0.2% with rate control; p=0.007), QT prolongation (1.9% versus 0.3%; p<0.001) and bradycardic events than a strategy of rate control.[121] (**1+**)

In patients with recurrent AF, a strategy of rhythm control is associated with a higher rate of adverse pulmonary events (7.3% in rhythm control, 1.7% in rate control; p<0.001), gastrointestinal events (2.7% in rhythm control, 2.1% in rate control; p<0.001) or other non-cardiac adverse events (25.4% in rhythm control, 14.0% in rate control; p<0.001) than a strategy of rate control.[121] (**1+**)

In patients with recurrent AF, a strategy of rhythm control is associated with a higher rate of hospital admissions than is a strategy of rate control (54% versus 26%; p<0.001,[119] 74% versus 12%; p<0.001,[122] 80% versus 73%; p<0.001).[121] (**1+**)

In patients with recurrent AF, no significant difference has been found in quality of life,[120] myocardial infarction[121] or development of congestive heart failure[121] between strategies of rate control and rhythm control (**1+**); however, two studies did record a significant improvement in the level of physical functioning in both treatment groups.[119,120] (**1+**)

In patients with recurrent AF, no significant difference has been found in 5-year cumulative rates of thromboembolic or haemorrhagic events between strategies of rate control and rhythm control.[121] (**1+**)

The rate-control strategy cost US$5,077 less per person than the rhythm-control strategy (US$20,546 versus US$25,623).[125] Using low and high cost estimates in the sensitivity analysis, rate control saved from US$2,189 to US$5,481 per person. Including the mean survival gain of 0.08 of a year in rate control using original trial data, the rate-control strategy was both less costly and more effective and therefore is preferable to rhythm control.

In a study conducted in the Netherlands the rate-control strategy cost €898 less per person than the rhythm-control strategy (€7,386 versus €8,284).[126] Based on the difference in primary endpoints (cardiovascular morbidity or mortality) in rate versus rhythm control (17.5% versus

21.2%) from original trial data, rate control saves €24,944 per endpoint avoided. The higher costs with rhythm control were attributed to ECV, hospital admissions and antiarrhythmic medication.[126]

6.1.3 From evidence to recommendations

No study found rate control to be inferior to rhythm control or vice-versa for the outcome measures of mortality[118–122] or quality of life.[120] However, one study[121] found mortality to be higher for rhythm control in those with coronary heart disease, those without heart failure and those over 65 years old. The same study did not find rhythm control to be associated with lower mortality in those with heart failure.

Rates of hospitalisation, as well as rates of adverse events, were higher among participants treated with rhythm-control treatment plans.[119,121,122] The results were generally consistent across studies and considered older participants with elevated risk of stroke,[118,121] as well as younger participants.[120,122]

It was felt that many of the stroke and thromboembolic events in the rhythm-control arm were related to the lack of appropriate use of antithrombotic therapy. Rates of anticoagulation were often not controlled between the two treatment arms in many of the studies. For example, in one study[121] anticoagulation was mandatory in the rate-control treatment arm, but in the rhythm-control arm continuous anticoagulation was encouraged but could be stopped at the physician's discretion if sinus rhythm had apparently been maintained for at least 4 (and preferably 12) consecutive weeks. Anticoagulation therapy use may have had some effect on the outcome of the study, and in a subsequent post hoc analysis,[127] the use of anticoagulation therapy was an independent predictor of survival.

Although one study[121] reported a higher incidence of adverse pulmonary events associated with rhythm control, it was not reported whether this was due to the particular choice of rhythm-control drug used rather than the strategy itself.

The health economic evidence concluded that a rate-control strategy was more cost-effective than a rhythm-control strategy. However, it was unclear whether the UK setting and outcome costs of inadequate anticoagulation would affect the results.

RECOMMENDATIONS

R11 As some patients with persistent AF will satisfy criteria for either an initial rate-control or rhythm-control strategy (for example, aged over 65 but also symptomatic):

- the indications for each option should not be regarded as mutually exclusive and the potential advantages and disadvantages of each strategy should be explained to patients before agreeing which to adopt
- any comorbidities that might indicate one approach rather than the other should be taken into account
- irrespective of whether a rate-control or a rhythm-control strategy is adopted in patients with persistent AF, appropriate antithrobotic therapy should be used. **D(GPP)**

R12 A rate-control strategy should be the preferred initial option in the following patients with persistent AF:

- over 65 years old **B**
- with coronary artery disease **B**
- with contraindications to antiarrhythmic drugs **D(GPP)**
- unsuitable for cardioversion* **D(GPP)**
- without congestive heart failure. **B**

R13 A rhythm-control strategy should be the preferred initial option in the following patients with persistent AF:

- those who are symptomatic **D(GPP)**
- younger patients **C**
- those presenting for the first time with lone AF **D(GPP)**
- those with AF secondary to a treated/corrected precipitant **D(GPP)**
- those with congestive heart failure. **C**

*Patients unsuitable for cardioversion include those with:

- contraindications to anticoagulation
- structural heart disease (eg large left atrium >5.5 cm, mitral stenosis) that precludes long-term maintenance of sinus rhythm
- a long duration of AF (usually >12 months)
- a history of multiple failed attempts at cardioversion and/or relapses, even with concomitant use of antiarrhythmic drugs or non-pharmacological approaches
- an ongoing but reversible cause of atrial fibrillation (eg thyrotoxicosis).

6.2 Rhythm control for persistent AF

In persistent AF, antiarrhythmic drugs are prescribed to increase the likelihood of maintaining sinus rhythm following successful electrical or pharmacological cardioversion.

The use of antiarrhythmic drugs to maintain sinus rhythm post cardioversion is addressed in this section. In UK clinical practice, prophylactic drug treatment is not usually used in cases of a first-detected episode of AF, especially if AF is secondary to a precipitant that has since been corrected. Without antiarrhythmic drugs, the recurrence rate is high. Reversible cardiovascular and non-cardiovascular precipitants of AF are usually actively managed first. Predictors of recurrences of AF are considered elsewhere (see section 12.2).

Clinical studies have shown the efficacy of various antiarrhythmic drugs (amiodarone, propafenone, disopyramide, sotalol, flecainide, quinidine and azimilide) against no treatment, placebo or digoxin.[64,68,128] It is clear from these trials that the use of antiarrhythmic drugs does improve maintenance of sinus rhythm post cardioversion. But despite treatment, relapse to AF occurs in approximately 50% of patients by 12 months (see section 12.2). Moreover, the need for antiarrhythmic drugs has to be balanced against adverse effects and a higher mortality in some patients.[129]

UK clinical practice commonly uses Class Ic, beta-blockers or Class III antiarrhythmic drugs to maintain sinus rhythm, and this section compares their relative efficacy.

6.2.1 Methodological introduction

The literature search and evidence appraisal processes for this question resulted in 12 studies being included in this evidence report.

Studies were considered for inclusion if the efficacy of antiarrhythmic drugs was measured in a study population or subpopulation with a history of AF requiring electrical or chemical cardioversion, and an indication for long-term antiarrhythmic therapy for the maintenance of sinus rhythm.

Studies that consider the use of antiarrhythmic therapy specifically for reducing the frequency of recurrent episodes of AF in those patients with a history of paroxysmal AF are considered elsewhere (see section 8.1).

All but two[111,130] of the studies included in this report were RCTs.

No studies compared the efficacy of amiodarone, flecainide or propafenone with a beta-blocker such as metoprolol. However, five studies[89,111,131–133] compared amiodarone with the Class III beta-blocker sotalol, and three studies[134–136] compared propafenone with sotalol. Two studies[130,137] compared a Class Ic agent (flecainide or propafenone) with amiodarone. One study[112] compared amiodarone with either sotalol or propafenone, and one study[138] compared sotalol with the beta-blocker bisoprolol.

All studies except one[138] explicitly excluded patients with severe heart failure. Most also excluded those with moderate heart failure (typically defined as an NYHA grade greater than II).

Most of the studies were not powered to detect clinically significant differences in drug side effects, and many reported the composite endpoint of either recurrence of AF or occurrence of a drug-related side effect or drug withdrawal.

6.2.2 Evidence statements

▷ Sotalol versus propafenone

Two studies[134,135] found no difference in the proportion of patients with AF maintaining sinus rhythm at 12 months between sotalol and propafenone (**1+**). One study[135] also found a similar result when only those subgroups with a history of paroxysmal or persistent AF were considered. (**1+**)

One study[136] found propafenone resulted in a lower incidence of side effects or AF recurrence than sotalol (52% versus 81%; $p<0.001$). (**1+**)

▷ Sotalol versus amiodarone

Three studies[89,131,132] found amiodarone to be significantly associated with an increased likelihood of remaining in sinus rhythm compared with sotalol at 12[89,131,132] and 24[132] months following cardioversion (**1++**). Similar results were found for the likelihood of remaining in sinus rhythm without side effects[111,132] and the monthly incidence of AF recurrence or side effects.[133] (**1+**)

One study[89] also found amiodarone to be associated with an increased likelihood of remaining in sinus rhythm compared with sotalol regardless of the duration of AF and whether or not the AF was associated with symptoms (**1++**). However, the study found no significant difference between the two drugs in those patients with ischaemic heart disease. (**1++**)

▷ Sotalol versus beta-blockers

One study[138] found no difference in the percentage of patients with recurrent AF during a mean follow-up period of approximately 8 months between 5 mg/day bisoprolol and 160 mg/day sotalol (42% versus 41%) (**1+**). There were two cases of proarrhythmia and two cases of bradycardia in the sotalol group and two cases of bradycardia in the bisoprolol group.

▷ Flecainide versus amiodarone

One study[130] of patients with recurrent AF found no significant difference in the efficacy of flecainide and amiodarone over a period of 3 months in terms of the rate of recurrent AF (38% versus 32%). (**2++**)

▷ Propafenone versus amiodarone

One study[112] comparing either propafenone or sotalol with amiodarone found amiodarone to be associated with a higher proportion of patients remaining in sinus rhythm after an average follow-up period of 468 days (39% versus 69%; $p<0.001$) (**1+**). Sotalol and propafenone were similar in terms of efficacy. Amiodarone was also associated with a lower incidence of drug-related side effects requiring discontinuation compared with sotalol/propafenone (46% versus 34%; $p=0.01$), although the incidence of drug discontinuation between the propafenone and sotalol patients was not reported separately. (**1+**)

One study[137] found no significant difference between propafenone and amiodarone in terms of the percentage of patients maintaining sinus rhythm over 24 months (52% versus 59%; $p=0.058$) (**1+**). When the composite outcome of remaining in sinus rhythm without side effects was considered, the two drugs were similar (51% versus 42%; $p=0.44$). (**1+**)

6.2.3 From evidence to recommendations

An escalating approach to drug therapy could be recommended based on associated comorbidity and the need for increasingly effective antiarrhythmic drugs. For example, a beta-blocker or sotalol could be prescribed in the first instance, and where this was not tolerated, or was ineffective, other drugs could be administered.

This escalation of drug use is not totally in keeping with the evidence on efficacy, which is in favour of amiodarone, but also incorporates concerns regarding the adverse effects. In the case of amiodarone, such adverse effects may become apparent only after long-term use and include pulmonary, hepatic, ophthalmic and thyroid toxicity.

RECOMMENDATIONS

R14 An antiarrhythmic drug is not required to maintain sinus rhythm in patients with persistent AF in whom a precipitant (such as chest infection or fever) has been corrected and cardioversion has been performed successfully, providing there are no risk factors for recurrence. **D(GPP)**

R15 In patients with persistent AF who require antiarrhythmic drugs to maintain sinus rhythm and who have structural heart disease*:

- a standard beta-blocker should be the initial treatment option **D(GPP)**
- where a standard beta-blocker is ineffective, contraindicated or not tolerated amiodarone should be used. **A**

R16 In patients with persistent AF who require antiarrhythmic drugs to maintain sinus rhythm and who do not have structural heart disease*:

- a standard beta-blocker should be the initial treatment option **D(GPP)**
- where a standard beta-blocker is ineffective, contraindicated or not tolerated
  - a Class Ic agent or **C**
  - sotalol** **D(GPP)**

should be given

- where other drug classes are ineffective, contraindicated or not tolerated amiodarone should be administered. **B**

*Coronary artery disease or left ventricular dysfunction.
**Progressively titrated from 80 mg twice daily up to 240 mg twice daily.

6.3 Antithrombotic therapy for persistent AF

Patients with persistent AF may be treated with either a rate-control or rhythm-control treatment strategy. Where a rhythm-control treatment strategy is chosen, there is the need for appropriate use of antithrombotic therapy to prevent acute stroke or other thromboembolic events occurring during or shortly after cardioversion. Where a rate-control strategy is chosen, patients should be treated as outlined for permanent AF (see Chapter 7).

It is known that the presence of AF increases the risk of thromboembolic stroke,[13] but it is less clear whether this risk can be reduced by cardioversion (ECV or PCV) to normal sinus rhythm, assuming sinus rhythm is maintained and antithrombotic therapy is continued. The rate- versus rhythm-control trials have not resolved this issue as many of the patients relapsed into AF and had been administered inadequate thromboprophylaxis (see section 6.1).

Appropriate thromboprophylactic measures are essential in patients considered for cardioversion since it has been shown that cardioversion of AF of more than 48 hours duration increases the short-term (peri-cardioversion) risk of stroke and thromboembolism.[139,140] Data from the rate-control versus rhythm-control trials suggest that consideration should be given to long-term anticoagulation in patients at high risk of stroke and/or AF recurrence in view of the frequent asymptomatic recurrences of the arrhythmia leading to thromboembolism in the presence of risk factors.[65]

In the past, there have been no prospective randomised placebo-controlled trials testing the efficacy of anticoagulation (versus placebo) in the prevention of peri-cardioversion thromboembolism, but several retrospective studies and/or case series have suggested benefit from the use of therapeutic warfarin in this setting. Cardioversion of atrial flutter presents similar risks and requires similar anticoagulation.

The administration of antithrombotic therapy peri-cardioversion applies to both electrical and pharmacological cardioversion strategies.

Apart from the periods leading up to and following cardioversion, there is no evidence to suggest that the choice of antithrombotic therapy should be any different from that recommended for patients with permanent AF (see section 7.2).

6.3.1 Methodological introduction

The results of a meta-analysis of 25 primary studies[141] and three primary studies[142–144] are included in this report. Only one[144] of the primary studies was a RCT.

The meta-analysis included in this report[141] pooled the results of multiple primary studies comparing the effectiveness of anticoagulation or the effectiveness of TOE screening for the prevention of acute embolic events (ischaemic stroke or transient ischaemic attack or systemic embolism) post cardioversion.

None of the studies examined rates of thromboembolism in emergency versus elective cardioversion, and in particular whether acute anticoagulation with heparinoids is an effective means of stroke prevention in comparison to oral anticoagulation.

No studies compared the effectiveness of any form of anticoagulation post cardioversion against placebo or the effectiveness of antiplatelet agents against either anticoagulation or placebo.

6.3.2 Evidence statements

Based on the results of two primary studies[142,143] and one meta-analysis,[141] anticoagulation prior to cardioversion has been found to be associated with a reduced rate of thromboembolic complications post cardioversion when compared with no anticoagulation. (**2++**)

Anticoagulation reaching an international normalised ratio (INR) greater than 2.0 at the time of cardioversion has been found to be associated with a significantly lower rate of thromboembolic complications 4 weeks post cardioversion when compared with lower values (including those receiving no anticoagulation).[142,143] (**2+**)

Anticoagulation prior to cardioversion has been found to be associated with a reduced rate of acute thromboembolic complications post cardioversion when compared with TOE screening for the presence of thrombi prior to cardioversion and the exclusion of screen-positive patients.[141] (**2++**)

Anticoagulation with enoxaparin throughout the peri-cardioversion period is as effective as unfractionated heparin peri-cardioversion followed by oral anticoagulation with a coumarin derivative post cardioversion.[144] (**1+**)

6.3.3 From evidence to recommendations

Anticoagulation administered to a target INR of 2.5 (with a range of 2.0 to 3.0) prior to cardioversion is effective in reducing the frequency of acute thromboembolic complications post cardioversion. In studies involving anticoagulation to resolve any intracardiac thombi, a duration of 3 to 4 weeks prior to cardioversion has often been specified.[114,145] It was therefore considered necessary for anticoagulation to be therapeutic (within the INR range 2.0 to 3.0) for a minimum of 3 weeks prior to cardioversion for resolution or endothelisation of any pre-existing thrombus. In practice this may be verified as three consecutive weekly INR measurements within the therapeutic range.

Anticoagulation is more effective than screening patients for thrombi using TOE alone as a means of reducing the frequency of thromboembolic complications of cardioversion.[141]

Based on a period of 4 weeks for the return of atrial contractile function post cardioversion, it was considered that anticoagulation should remain at therapeutic levels throughout this time. Even in patients with a successful cardioversion, evidence from the AFFIRM study[121,127] suggests that longer-term anticoagulation may be necessary in the presence of stroke and thromboembolism risk factors (see section 11.6) or risk factors for AF recurrence (see section 12.2). The evidence from AFFIRM showed that, although sinus rhythm is associated with reduced mortality, patients enrolled in the rhythm-control treatment strategy had a similar incidence of stroke to those in the rate-control treatment strategy.

It is noteworthy that many of the risk factors for thromboembolism in AF are similar to those for AF recurrence.

RECOMMENDATIONS

R17 Before cardioversion, patients should be maintained on therapeutic anticoagulation with warfarin (INR 2.5, range 2.0 to 3.0) for a minimum of 3 weeks. **C**

R18 Following successful cardioversion, patients should remain on therapeutic anticoagulation with warfarin (INR 2.5, range 2.0 to 3.0) for a minimum of 4 weeks. **D(GPP)**

R19 In patients with persistent AF where cardioversion cannot be postponed for 3 weeks:

- heparin should be given and the cardioversion performed, and **D**
- warfarin should then be given for a minimum of 4 weeks post cardioversion. **D(GPP)**

R20 Anticoagulation should be continued for the long term in patients with AF who have undergone cardioversion where there is a high risk or AF recurrence* or where it is recommended by the stroke risk stratification algorithm (Figure 11.1). **D(GPP)**

R21 In patients with AF of confirmed duration of less than 48 hours undergoing cardioversion, anticoagulation following successful restoration of sinus rhythm is not required. **D(GPP)**

R22 Patients with atrial flutter should be given antithrombotic therapy in the same manner as those with AF. **D(GPP)**

*Factors indicating a high risk of AF recurrence include:

- a history of failed attempts at cardioversion
- structural heart disease (mitral valve disease, left ventricular dysfunction or an enlarged left atrium)
- a prolonged history of AF (greater than 12 months)
- previous recurrences of AF.

6.4 Rhythm-control treatment algorithm for persistent AF

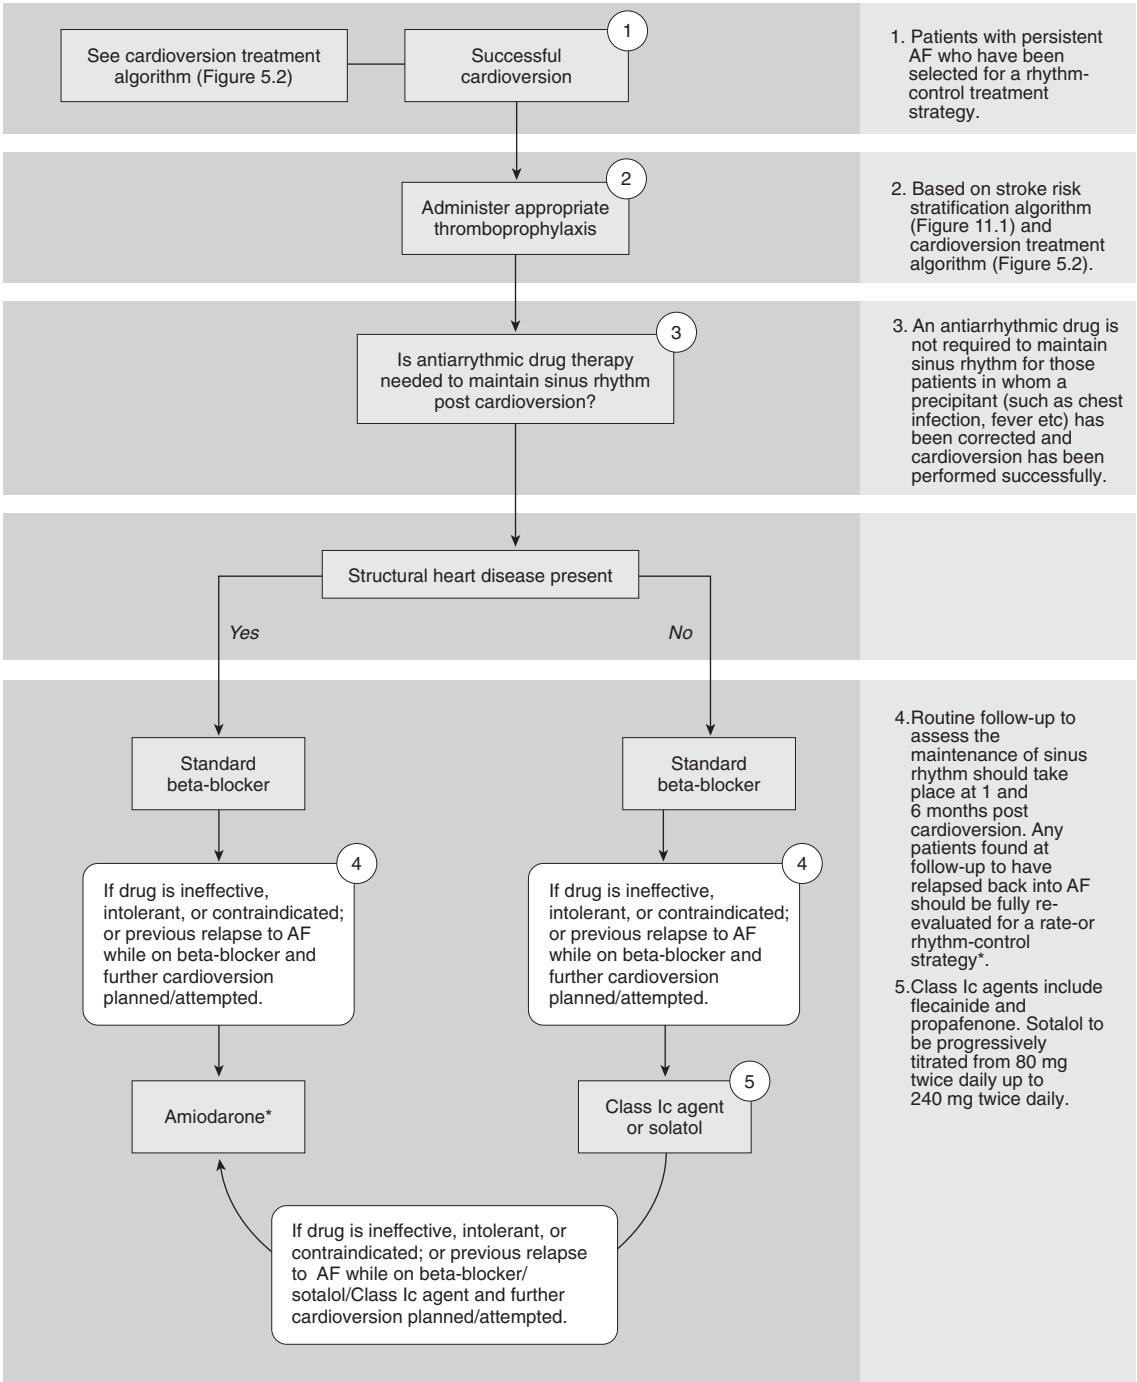

Figure 6.1 Rhythm-control treatment algorithm for persistent AF. *If rhythm control fails, consider the patient for rate-control strategy or specialist referral in those with lone AF or ECG evidence of underlying electrophysiological disorder (eg Wolff–Parkinson–White syndrome).

7 Treatment for permanent AF

7.1 Rate control for permanent AF

The aims of heart rate control are to minimise symptoms associated with excessive heart rates and prevent tachycardia-associated cardiomyopathy.[146] A recent consensus[147] statement has suggested a target resting heart rate of less than 90 bpm and less than 180 bpm during exercise in patients with AF.

Historically, cardiac glycosides such as digoxin have been used but have limited efficacy in a hyperadrenergic state such as thyrotoxicosis, fever, acute volume loss, postoperative state and during exertion.[148] In clinical practice, digoxin monotherapy may only be adequate for the older, sedentary patient.[149] Other agents for rate control include beta-blockers and the rate-limiting non-dihydropyridine calcium-channel blockers ('calcium antagonists') such as diltiazem and verapamil. These are used for rate control, both at rest and during exercise, and are perceived to be more effective than digoxin in the critically ill.[65,150] Diltiazem is regarded as preferable to verapamil, in view of the latter's negative inotropic effect and potential drug interaction with digoxin. Beta-blockers and calcium antagonists may also worsen acute heart failure.

One short acting intravenous beta-blocker, esmolol, is useful when oral drugs cannot be given or if there is uncertainty over tolerance of the beta-blocker.

Rate control may not always be achieved with a single drug. Combination therapy, for example digoxin plus a beta-blocker or rate-limiting calcium-channel blocker is often considered for AF uncontrolled with a single agent. If these two classes of drugs are ineffective or not tolerated, amiodarone or diltiazem-beta-blocker combination therapy are third-line pharmacological options used by specialists. Alternatively, a non-pharmacological approach (mainly atrio-ventricular node ablation coupled with pacing) can be considered, but is beyond the scope of this review.

7.1.1 Methodological introduction

This section considered the efficacy of:

- beta-blockers,
- digoxin and
- calcium antagonists.

Of the 12 studies that were included, all but one[151] were either randomised or serial crossover trials. Consequently, the total number of participants was relatively low.

For the comparison of calcium antagonists and beta-blockers, three studies were found, one of which[152] used the beta-blocker betaxolol, which is not available orally in the UK. In this and a second study,[153] the patients were also receiving digoxin, which may have confounded the results.

There is consistency in the results between different drugs within the same class for both the comparison of calcium antagonists versus digoxin and beta-blockers versus digoxin.

7.1.2 Evidence statements

▷ Calcium antagonists versus digoxin

Seven studies[154–160] found no difference in average heart rate between calcium antagonists verapamil or diltiazem and digoxin either at rest or during periods of normal daily activity (**1++**). However, seven studies[153,155–160] found calcium antagonists resulted in a lower heart rate during exercise, compared with digoxin. (**1++**)

▷ Beta-blockers versus digoxin

Three studies[151,154,161] found no difference in average heart rate between digoxin and beta-blockers while at rest or during periods of normal daily activity (**1++**). However, the beta-blockers atenolol[154] and labetalol[161] controlled heart rate during exercise more effectively than digoxin did (**1++**). One additional study[153] found that atenolol significantly reduced average heart rate in comparison to digoxin both at rest and after exercise. (**1+**)

▷ Beta-blockers versus calcium antagonists

One crossover study[154] found no difference between the calcium antagonist diltiazem and the beta-blocker atenolol in terms of either the mean heart rate over 24 hours or during exercise (**1+**). A second crossover study[153] found no difference in the mean heart rate at rest or post-exercise between the calcium antagonist verapamil and atenolol (**1+**). However, a third study[152] found the beta-blocker betaxolol to be more effective than diltiazem both over 24 hours and during exercise. (**1+**)

▷ Beta-blockers with digoxin versus beta-blockers

One crossover study[154] found the beta-blocker atenolol used in combination with digoxin to be associated with a lower heart rate over 24 hours than atenolol alone (**1+**). In another study[161] using the beta-blocker labetalol the reported differences were not statistically significant (**1++**). Neither study found any statistically significant differences in heart rate during periods of exercise. (**1++**)

▷ Calcium antagonists with digoxin versus calcium antagonists

Four crossover studies[154,156,159,162] found the calcium antagonists diltiazem or verapamil used in combination with digoxin to be more effective in controlling heart rate over 24 hours, as well as during periods of exercise, than either diltiazem or verapamil alone. (**1++**)

7.1.3 From evidence to recommendations

When used as monotherapies, both calcium antagonists and beta-blockers were more effective than digoxin in controlling heart rate at high levels of physical exertion, but there was no difference during normal daily activities. Based on the results of two studies there was no significant difference in terms of the effectiveness of heart rate control between calcium antagonists and beta-blockers.[152,154]

During rest the combination of beta-blockers with digoxin was more effective than beta-blockers alone for the control of heart rate.[154,161] The combination of calcium antagonists with digoxin was more effective than calcium antagonists alone for the control of heart rate both during normal activities and rest, as well as during exercise.[154,156,159]

None of the studies were sufficiently large to make comparisons in terms of side effects. In particular, no study reported any intolerance to beta-blockers.

RECOMMENDATIONS

R23 In patients with permanent AF, who need treatment for rate control:

- beta-blockers or rate-limiting calcium antagonists should be the preferred initial monotherapy in all patients **A**
- digoxin should only be considered as monotherapy in predominately sedentary patients. **D(GPP)**

R24 In patients with permanent AF where monotherapy is inadequate:

- to control the heart rate only during normal activities, beta-blockers or rate-limiting calcium antagonists should be given with digoxin **B**
- to control the heart rate during both normal activities and exercise, rate-limiting calcium antagonists should be given with digoxin. **B**

7.2 Antithrombotic therapy for permanent AF

The aim of antithrombotic therapy in patients with permanent AF is to prevent ischaemic stroke and other thromboembolic events. This section examines which type of antithrombotic therapy (anticoagulation, antiplatelet drugs or no treatment) has been shown to be effective in treating patients with permanent AF.

The high risk of ischaemic stroke and other thromboembolic events in AF has long been recognised. In particular, AF patients with valvular heart disease have an elevated risk of stroke and other thromboembolic events. Specifically, the presence of mitral valve stenosis has been shown to be a substantial risk for stroke and thromboembolism, with these events occurring in 9 to 20% of patients, of whom up to 75% have cerebral emboli.[163,164] A person with mitral stenosis in sinus rhythm who develops AF increases their risk of thromboembolism by three to seven times.[164,165] The risk of systemic emboli in rheumatic mitral disease is much greater in both the elderly and those with poor cardiac function, but correlates poorly with mitral valve calcification, mitral valve area, or left atrial size.

Percutaneous balloon mitral commissurotomy decreases the risk of systemic embolism, but mitral valvuloplasty does not appear to. Successful mitral valvuloplasty does not therefore eliminate the need for continued anticoagulation.[164] Because of the risk of stroke and thromboembolism, it has been considered unethical to conduct placebo-controlled trials of antithrombotic therapy in patients with mitral valve disease.

Similarly, the presence of AF without any valve disease (non-valvular AF) increases the risk of stroke and thromboembolism five-fold.[13] Silent cerebral infarction is also a common problem[166] and there is a distinct clustering of stroke events at the time of onset of AF as well.[167] In contrast

to valvular AF, however, in the past two decades many large randomised trials have examined the value of antithrombotic therapy in non-valvular AF.[168]

Because of the increasingly elderly population, AF is likely to become more common, and the issues associated with thromboprophylaxis will become an even greater public health problem. Despite the higher risk associated with stroke in the elderly, as well as the greatest benefit of anticoagulation, the elderly are the group of patients where there is suboptimal use of thromboprophylaxis for AF. This is thought to be because of the perceived increased risk associated with comorbidity, interactions with concomitant drug therapies and bleeding in these patients.[169] Suboptimal use of thromboprophylaxis may also be due to patient factors, where some patients choose the option of 'informed dissent' and decline an effective treatment option.[170]

The purpose of this section is to review the evidence on antithrombotic therapies (oral anti-coagulation and/or antiplatelet therapy) as a means of preventing stroke and thromboembolism in patients with permanent AF.

7.2.1 Methodological introduction

The results of eight meta-analyses, four RCTs and two unrandomised controlled trials of oral anticoagulation using vitamin K antagonists such as warfarin, and antiplatelet therapy in patients with AF were included. Results relating to the antiplatelet agent triflusal were included but no recommendations were made on this drug as it is not currently licensed for use in the UK.

Most of the trials were large randomised trials, consisting almost entirely of patients with permanent non-valvular AF.

7.2.2 Evidence statements

▷ Adjusted-dose warfarin versus placebo

Two studies,[171,172] found that compared with placebo, adjusted-dose warfarin was associated with a reduction in ischaemic stroke: (**1+**)

- ARR = 3.1% (62% RRR)[171]
- OR = 0.34 (95% CI 0.25 to 0.46).[172]

However, in one study adjusted-dose warfarin was found to be associated with an increased risk of major haemorrhage (OR 2.35, 95% CI 1.30 to 4.24)[172] (**1+**). The same study[172] also found no significant difference in terms of overall mortality (OR 0.74, 95% CI 0.53 to 1.04). (**1+**)

▷ Adjusted-dose warfarin versus control treatment (aspirin or placebo)

One study[173] found adjusted-dose warfarin (compared with aspirin or placebo controls) to be associated with a significant reduction in the incidence of ischaemic stroke as well as the composite outcomes of haemorrhagic or ischaemic stroke, and vascular events (myocardial infarction, stroke, haemorrhage, vascular death) (**1+**). The same study[173] also found no significant effect for the incidence of myocardial infarction, systemic embolism or intracranial haemorrhage (ICH). (**1+**)

▷ Adjusted-dose warfarin versus antiplatelet therapy (aspirin or indobufen)

Two meta-analyses[171,174] found adjusted-dose warfarin (compared with antiplatelet therapy with aspirin or indobufen) to be significantly associated with an absolute risk reduction of ischaemic stroke: (**1+**)

- ARR = 0.8% (36% RRR), p<0.05[171]
- ARR = 2.3% (2.0% versus 4.3%; p<0.001).[174]

One meta-analysis[174] found that when the composite outcome of either ischaemic stroke or ICH was considered, it resulted in an absolute risk reduction of 2.1% (2.4% versus 4.5%; p<0.001). (**1+**)

In one meta-analyses[174] adjusted-dose warfarin was found to be associated with an increase in incidence of major haemorrhage (increased absolute risk of 0.9% (2.2% versus 1.3%; p<0.05)), however, in a second meta-analysis no significant difference was found.[175] (**1+**)

One study[175] found adjusted-dose warfarin (compared with antiplatelet therapy with aspirin or indobufen) to be associated with a reduced incidence of non-fatal stroke, although no significant difference has been found for fatal stroke, nor overall mortality (**1+**). In another study,[176] adjusted-dose warfarin was found to be associated with a reduced incidence of severe ischaemic stroke in those where an ischaemic stroke occurs. (**2+**)

▷ Adjusted-dose warfarin versus fixed, low-dose warfarin

One meta-analysis[172] found adjusted-dose warfarin to be associated with a reduced risk of stroke (OR 0.38, 95% CI 0.24 to 0.60) compared with fixed, low-dose warfarin. In a second study[177] only the composite outcome of all thrombotic events was found to be significant (RR 0.50, 95% CI 0.25 to 0.97). (**1+**)

No significant difference has been found in the incidence of overall mortality,[172] vascular or haemorrhagic death[177] or major haemorrhage[172] between fixed, low-dose warfarin and adjusted-dose warfarin. (**1+**)

▷ Adjusted-dose warfarin versus fixed, low-dose warfarin with aspirin

One meta-analysis[172] found adjusted-dose warfarin (compared with fixed, low-dose warfarin) significantly reduced the incidence of stroke (OR 0.38, 95% CI 0.24 to 0.60). However a larger meta-analysis[177] found no significant difference (**1+**). No significant difference has been found in terms of overall mortality,[172] vascular or haemorrhagic death[177] or major haemorrhage[172] between fixed, low-dose warfarin with aspirin and adjusted-dose warfarin. (**1+**)

One study[176] found that at an INR greater than or equal to 2.0, adjusted-dose warfarin was associated with a reduced incidence of severe ischaemic stroke in those where an ischaemic stroke occurs compared with when the INR is less than 2.0. (**2+**)

▷ Antiplatelet therapy with aspirin or dipyridamole and placebo

Based on the results of two studies,[172,178] no significant difference has been found between antiplatelet therapy with aspirin or dipyridamole and placebo in terms of:

- overall mortality[172] (1+)
- vascular death[178] (1+)
- myocardial infarction[178] (1+)
- systemic embolism[178] (1+)
- vascular event[178] (1+)
- major haemorrhage.[172,178] (1+)

One meta-analysis[171] found antiplatelet therapy to be associated with an absolute risk reduction for stroke of 1.9% (24% relative risk reduction), however, in two smaller meta-analyses[172,178] no significant differences were found. (1+)

▷ Triflusal with acenocoumarol versus acenocoumarol monotherapy

One study[179] which compared triflusal (600 mg per day) in combination with acenocoumarol (INR of 1.25 to 2.00) with acenocoumarol monotherapy (INR of 2.0 to 3.0) found that the composite outcome of overall (haemorrhagic and ischaemic) stroke incidence, vascular death or systemic embolism was lower in the combination therapy group than in the acenocoumarol monotherapy group (0.92% per year versus 2.70% per year; $p<0.05$) (1+). A similar association was found when the number of severe bleeding events was added to the overall incidence of stroke or systemic embolism (1.48% per year versus 3.78% per year; $p<0.05$) (1+). No statistically significant difference was reported in the incidence of severe bleeding events. (1+)

7.2.3 From evidence to recommendations

The studies included wide variations in the dose of aspirin (75 mg to 325 mg per day). Similarly, the studies differed in the degree of anticoagulation, with earlier studies using a higher level of anticoagulation (INR range of 2.0 to 4.5) than more recent studies.

Oral anticoagulation with vitamin K antagonists (such as warfarin) was the most effective thromboprophylactic treatment in the prevention of cardioembolic stroke. A target INR of 2.5 (range 2 to 3) should be maintained for the majority of patients.[176] However, anticoagulation is associated with an increased rate of haemorrhagic stroke and other bleeding events.[172] Nonetheless, it remains effective for the prevention of stroke overall.[174,175] No association between anticoagulation and mortality has been found for either vascular-related deaths[173] or all forms of death.[172]

The true efficacy of warfarin prophylaxis may have been underestimated as most strokes in patients randomised to warfarin occurred when the patients were not taking warfarin or when they were significantly under-anticoagulated. Further underestimates may have risen from the inconvenience of dosing adjustments and the need for regular blood tests to monitor INR levels, dietary restrictions, the risk of minor and major bleeding, and under-appreciation or lack of knowledge of the risk of stroke, or they may not adhere strictly to the treatment regimen, thereby placing themselves at greater risk for stroke or a major bleed.[169,180]

The dose of aspirin for AF thromboprophylaxis is subject to controversy. The relative stroke risk reduction of aspirin in AF patients is approximately 22%.[171] This is similar to that seen in a general population and the reduction of vascular events (22%) for antiplatelet therapy versus

control in 'high risk' patients with vascular disease.[181] Moreover, in the latter cases no differences have been reported in aspirin doses between 75 to 325 mg.[181] However, higher aspirin doses may be associated with more adverse effects.

AF commonly co-exists with vascular disease, and the benefits of aspirin in AF may simply relate to the effect on vascular disease, rather than on thrombogenesis in AF *per se*. This is supported by the thrombi associated with AF being fibrin rich ('red clot') and more related to coagulation abnormalities.

In trials specifically of AF populations comparing aspirin with placebo, the one trial[182] that tested aspirin 75 mg/day did not show a significant benefit for the prevention of stroke in patients with permanent AF. Similarly, in another trial[183] aspirin (most at 325 mg per day) was given in a non-randomised manner, and no significant benefit was seen. However, in another trial[184] using aspirin 325 mg/day, aspirin was reported to result in a significant 42% reduction in stroke, but was best for those aged under 75 years and did not prevent severe strokes or recurrent strokes.

Because aspirin 325 mg tablets are unavailable in the UK, and in view of the controversy over trial evidence in relation to the pathophysiological data, it was considered reasonable to recommend the use of aspirin at a dose of 75 to 300 mg/day as thromboprophylaxis.

It was noted that the addition of aspirin to oral anticoagulation (warfarin or fluindione) produced no extra benefit for stroke prevention but may increase bleeding risk. It was therefore felt that to prevent strokes in patients with AF, aspirin should not be given as adjunctive therapy to warfarin although there may be other reasons for co-prescribing aspirin. For example, aspirin 75 mg a day is commonly prescribed for vascular disease (eg carotid, coronary or peripheral artery disease), and if AF is also present, warfarin – if indicated for stroke prevention – is also commonly given. It is a matter for clinical judgement on the appropriateness, duration and safety (eg risk of bleeding) of the concomitant administration of warfarin with aspirin. It was noted that another antiplatelet agent (trifusal, not available in the UK) was of benefit when administered together with the oral anticoagulant acenocoumarol.

It was stressed that the risk of stroke and thromboembolism in AF patients is not homogeneous, and risk stratification is essential (see section 11.6).

RECOMMENDATIONS

R25 In patients with permanent AF a risk–benefit assessment should be performed and discussed with the patient to inform the decision whether or not to give antithrombotic therapy. **D(GPP)**

R26 In patients with permanent AF where antithrombotic therapy is given to prevent strokes and/or thromboembolism (see section 11.6):

- adjusted-dose warfarin should be given as the most effective treatment **A**
- adjusted-dose warfarin should reach a target INR of 2.5 (range 2.0 to 3.0) **A**
- where warfarin is not appropriate, aspirin should be given at 75 to 300 mg/day **B**
- where warfarin is appropriate, aspirin should not be co-administered with warfarin purely as thromboprophylaxis, as it provides no additional benefit. **B**

7.3 Rate-control treatment algorithm for permanent AF

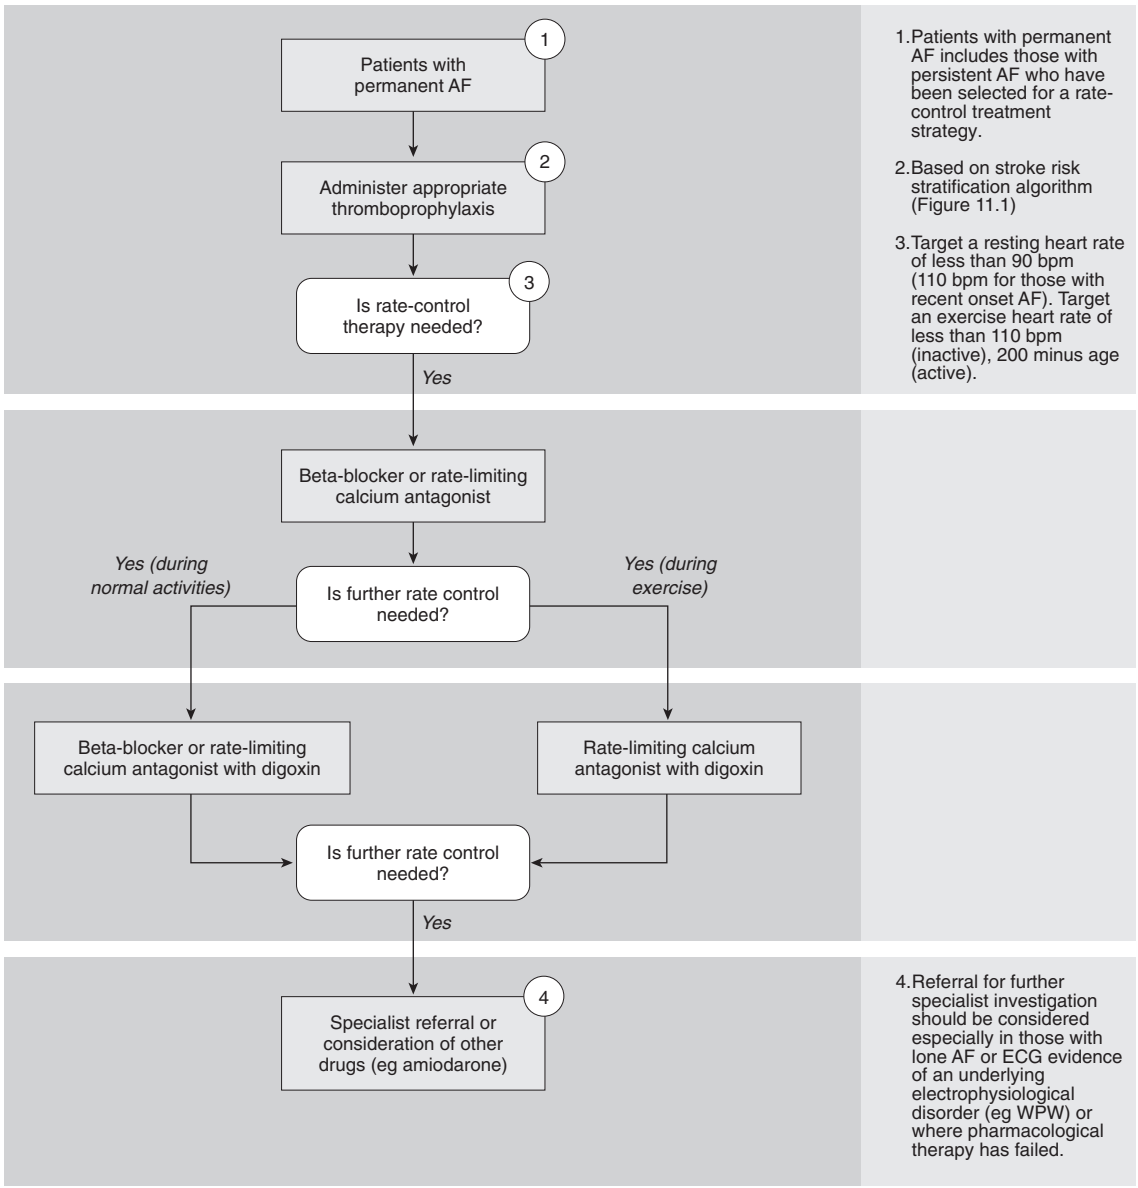

Figure 7.1 Rate-control treatment algorithm for permanent (and some cases of persistent) AF

8 Treatment for paroxysmal AF

8.1 Rhythm control for paroxysmal AF

The three main aims of treatment for paroxysmal AF are:

(i) to suppress paroxysms of AF and maintain long-term sinus rhythm

(ii) to control heart rate during paroxysms of AF if they occur

(iii) to prevent the complications associated with paroxysmal AF, ie stroke- and tachycardia-induced cardiomyopathy.[185]

This section of the guideline essentially deals with the first aim.

Many patients with paroxysmal AF can be highly symptomatic.[31] Paroxysms of AF that are persistent (that is, lasting more than 7 days) can be considered for cardioversion to sinus rhythm (see Chapter 5).

However, the abolition of symptoms of paroxysmal AF does not necessarily mean abolition of the AF *per se*, as heart rate slowing may abolish symptoms but allow asymptomatic episodes to continue.[186] In patients with symptomatic recurrences, it may be appropriate to document the frequency of arrhythmia by Holter monitoring or event recording (see section 4.4 above). If symptoms are abolished by therapy, repeat monitoring to ascertain whether asymptomatic episodes of AF are present is occasionally performed.

If attacks of paroxysmal AF are frequent, in current clinical practice chronic prophylaxis is usually used with drugs to reduce the frequency of paroxysms after removal of precipitating factors such as caffeine, alcohol, stress, and adequate treatment of underlying diseases such as myocardial ischaemia, thyrotoxicosis and heart failure.[185] If episodes of paroxysmal AF are infrequent, a pill-in-the-pocket approach can be considered (see section 8.2).

In the long term, few patients achieve complete suppression of paroxysms of AF. In clinical practice, clinicians commonly use beta-blockers or low-dose sotalol as first-line drugs, and if the patient is still getting symptomatic paroxysms, Class Ic and III drugs are used, depending on associated comorbidity and structural heart disease.

In UK clinical practice, the drugs commonly used for paroxysmal AF are beta-blockers, Class Ic agents (flecainide, propafenone) and Class III agents (sotalol, amiodarone). This section addresses the comparative efficacy of these agents.

8.1.1 Methodological introduction

Studies were considered for inclusion in this report if results were reported for a population or subpopulation with paroxysmal AF. Studies were excluded if the treatment drugs were not prescribed as regular medication for paroxysmal AF.

Nine studies were appraised, two[187,188] were entirely comprised of paroxysmal AF patients, although the follow-up times were relatively short (12 months or less) compared with other

studies in a general AF population. The remaining studies were undertaken in general AF populations and either reported the results for those with paroxysmal AF separately, or reported no significant interaction between AF type and drug efficacy, hence allowing extrapolation of the results to those with paroxysmal AF only.

All of the studies were either single-blinded or double-blinded RCTs with two active treatment arms. Studies that made comparisons with placebo or digoxin were not considered. All of the studies excluded patients with moderate-to-severe heart failure (typically defined as an NYHA grade greater than II).

One study based in Canada compared the costs of amiodarone treatment with propafenone/sotalol treatment.[189] The cost analysis was based on 1-year follow-up data of 392 patients randomised to low-dose amiodarone (200 mg/day) or alternative first-line therapy (sotalol or propafenone) in a multicentre open label trial.[112]

8.1.2 Evidence statements

▷ Propafenone versus sotalol

One study[187] found no significant difference in the proportion of patients experiencing a reduction in recurrent AF episodes between propafenone and sotalol (80 to 160 mg bid) over a minimum of 3 months. (**1++**)

One study[136] showed a significant difference in terms of the proportion of patients maintaining sinus rhythm between propafenone and sotalol (up to 480 mg/day) in favour of propafenone after 25 months of administration (**1+**). However, over shorter periods two other studies[134,135] found no significant difference. (**1++**)

One study[187] involving both persistent and paroxysmal AF participants found no significant difference in the rates of either intolerable or tolerable side effects between sotalol (80 to 160 mg bid) and propafenone. (**1++**)

▷ Amiodarone versus sotalol

Two studies involving subgroups of patients with paroxysmal AF[132,133] found amiodarone to be significantly associated with a lower rate of AF recurrence[133] and a higher prevalence of sinus rhythm[132] at 12 months and at 24 months compared to sotalol (160 to 480 mg/day[132] or 160 to 320 mg/day[133]). (**1+**)

▷ Beta-blockers versus sotalol

One small, open-label crossover study[188] found no significant difference between atenolol and sotalol (80 mg bid) in the frequency of recurrent episodes of AF or the average duration of recurrent episodes. (**1+**)

▷ Propafenone versus amiodarone

One study,[112] in a population of both persistent and paroxysmal AF patients, found amiodarone to be significantly associated with a higher prevalence of sinus rhythm at a mean

follow-up of approximately 15.6 months compared with propafenone or sotalol (69% versus 39%, respectively; p<0.001) (1+). The same study also reported comparable efficacy between propafenone and sotalol, as well as comparable outcomes in each arm of the study for paroxysmal and persistent AF patients (1+). In another study[137] involving a subgroup of 92 patients with paroxysmal AF, 40% of those treated with amiodarone had a recurrence of AF at 24 months, compared with 83% of those treated with propafenone (p=0.19) (1+). When the composite endpoint of either AF recurrence or occurrence of side effects was considered, the figures were 58% versus 53%, respectively (p=0.51). (1+)

One study[189] found that the average cost per patient for AF-related procedures and hospitalisations was significantly lower in the amiodarone group than the sotalol/propafenone group (US$532 versus US$898, p=0.03). This cost advantage increased when the costs of hospitalisations associated with strokes were included (US$541 versus US$947, p=0.02). However, the total mean hospital costs (US$1,854 versus US$1,834, p=0.96) and the total mean hospital costs plus physician costs (US$2,586 versus US$2,482, p=0.83) were similar in both groups.

8.1.3 From evidence to recommendations

Much of clinical practice in the management of paroxysmal AF has been based on relatively small trials of short duration in (mainly) symptomatic subjects. Most pharmacological studies of paroxysmal AF have concentrated on the reduction of symptomatic recurrences of paroxysmal AF, despite many having asymptomatic episodes. Many studies have also involved mixed populations with paroxysmal AF, paroxysmal atrial flutter or persistent AF.

Those patients who are asymptomatic or have rare paroxysms (eg only a few paroxysms a year) may decide not to take routine medication or to use a pill-in-the-pocket strategy, and the patient's views need to be considered. Similarly, where paroxysms are induced by precipitants (eg caffeine or alcohol), these need to be avoided by the patient, in which case treatment may not be necessary or a pill-in-the-pocket strategy could be adopted.

An escalating approach to drug therapy in paroxysmal AF could be recommended depending on the frequency of a patient's paroxysms and the need for increasingly effective antiarrhythmic drugs. For example, a beta-blocker could be prescribed in the first instance and in patients where this did not adequately control the paroxysms a Class Ic drug could be administered followed by amiodarone as a third-line option. This escalation of drug use is in the opposite direction of the evidence on efficacy alone as this did not fully cover the issue of the side effects (especially long-term) of the more efficacious agents.

Propafenone appeared to be at least as effective as sotalol in preventing the recurrence of AF for up to 12 months following administration,[134,187] although for longer periods propafenone was more effective.[136] The two drugs were comparable in terms of side effects.[187] It was noted that Class Ic agents (propafenone and flecainide) should be used with caution in patients with structural heart disease or coronary artery disease.

Amiodarone was more effective than sotalol[132,133] and propafenone[112] in the prevention of recurrent AF. Due to concerns regarding contraindications of Class Ic agents in patients with left ventricular dysfunction, amiodarone was regarded as the drug of choice in these patients with symptomatic paroxysms despite initial beta-blocker therapy.

The concerns over the long-term toxicity of amiodarone were not addressed in the evidence. Although the clinical evidence demonstrated that amiodarone was the most effective drug, its long-term use in patients with infrequent paroxysms needed to be fully weighed against the risk of side effects, especially since some (eg lung fibrosis) could be serious.

The advice given in the *British National Formulary* suggested that Class I and III agents should be administered under a hospital physician, but it was stressed that this did not necessarily mean that the patient had to be hospitalised and it was the decision to administer the drug that required the necessary expertise.

The evidence only addressed the suppression of paroxysms and did not cover the control of heart rate or the prevention of complications from paroxysmal AF (eg stroke). It was considered important that patients have their symptoms and medication reviewed regularly to determine whether a patient:

- had any side effects
- had a continued need for treatment
- could have their medication dose reduced.

It was also considered important that patients should not be left on medication long-term without review.

In terms of the cost of AF, amiodarone was cheaper than sotalol or propafenone, although this was based on a one-year follow-up study and costs of side effects may not have been adequately included in the analysis.

RECOMMENDATIONS

R27 Where patients have infrequent paroxysms and few symptoms, or where symptoms are induced by known precipitants (such as alcohol, caffeine), a 'no drug treatment' strategy or a pill-in-the-pocket strategy should be considered and discussed with the patient. **D(GPP)**

R28 In patients with symptomatic paroxysms (with or without structural heart disease,* including coronary artery disease) a standard beta-blocker should be the initial treatment option. **D(GPP)**

R29 In patients with paroxysmal AF and no structural heart disease:*

- where symptomatic suppression is not achieved with standard beta-blockers, either
  - a Class Ic agent (such as flecainide or propafenone), or **D(GPP)**
  - sotalol** **D(GPP)**

  should be given.
- where symptomatic suppression is not achieved with standard beta-blockers, Class Ic agents or sotalol, either
  - amiodarone, or **B**
  - referral for non-pharmacological intervention (see section 12.3)

  should be considered. **A**

R30 In patients with paroxysmal AF and coronary artery disease:

- where standard beta-blockers do not achieve symptomatic suppression, sotalol should be given* **D(GPP)**
- where neither standard beta-blockers nor sotalol achieve symptomatic suppression, either
  - amiodarone, or **B**
  - referral for non-pharmacological intervention (see section 12.3) **A**

  should be considered.

R31 In patients with paroxysmal AF with poor left ventricular function:

- where standard beta-blockers are given as part of the routine management strategy and adequately suppress paroxysms, no further treatment for paroxysms is needed **D(GPP)**
- where standard beta-blockers do not adequately suppress paroxysms, either
  - amiodarone or **B**
  - referral for non-pharmacological intervention (see section 12.3) **A**

  should be considered.

R32 Patients on long-term medication for paroxysmal AF should be kept under review to assess the need for continued treatment and the development of any adverse effects. **D(GPP)**

*Coronary artery disease or left ventricular dysfunction.
**Progressively titrated from 80 mg twice daily up to 240 mg twice daily.

8.2 Treatment strategy for paroxysmal AF

In selected patients with recurrent paroxysmal AF, out-of-hospital initiation of antiarrhythmic drugs may be possible, allowing for earlier treatment, a shorter duration of AF and a presumed likelihood of restoring and maintaining sinus rhythm. A pill-in-the-pocket approach is used in those not taking drugs regularly due to infrequent symptoms/paroxysms, or can be taken as an 'extra' drug dose in those already on a low maintenance of that particular drug. This approach is different to the out-of-hospital use of antiarrhythmic drugs in patients with recurrent persistent AF, where the aim may be to achieve pharmacological cardioversion *per se* or to improve the likelihood of subsequent elective electrical cardioversion (see Chapter 5), or to maintain sinus rhythm (see section 6.1).

The main concern with a pill-in-the-pocket approach is the risk of proarrhythmia often associated with antiarrhythmic drugs. Thus, the pill-in-the-pocket approach has generally been advocated only in those patients with a low risk of proarrhythmia and other adverse side effects. Such patients are typically those with no structural heart disease, absence of heart failure or left ventricular dysfunction, and where there is evidence that the antiarrhythmic drug used has previously worked successfully with no adverse effects (eg after at least one inpatient trial of the drug administered as a single oral dose, under ECG monitoring).

The antiarrhythmic drugs amiodarone and propafenone have both been considered in a number of trials comparing the safety and efficacy of a single oral dose of the drug with the intravenous administration of the same drug.[82–85] In all of these trials, patients were selected

on the basis of relatively young age and the absence of any severe underlying structural heart disease. There was no incidence of ventricular proarrhythmia reported in either the intravenous or oral administration arms of these trials, and the incidence of successful cardioversion within 8 or 24 hours was comparable in most cases.

The objective of this section is to determine in which patients a single oral-dose antiarrhythmic drug may be safely used as a pill-in-the-pocket approach.

8.2.1 Methodological introduction

Studies were included if a comparison was made in terms of the safety, efficacy and impact on healthcare resources between the out-of-hospital self-administration of pharmacological cardioversion and the supervised, in-hospital administration in a well-defined patient cohort with either AF or supraventricular tachycardia (SVT). Studies were not included if the pharmacological agents were administered prophylactically.

Both of the included studies were based in Italy and compared the rates of hospital admission and emergency room treatment in a single cohort of patients in the period before and the period after the self-administration of antiarrhythmic drugs for the termination of either paroxysmal AF[190] or paroxysmal SVT.[191]

Neither study specified the treatment protocol during the period before the self-administration of antiarrhythmic drugs, or made a comparison between the two periods in terms of safety and efficacy.

8.2.2 Evidence statements

One study[190] found that the average number of admissions per month for emergency treatment was significantly lower during treatment of paroxysmal AF using a pill-in-the-pocket approach with Class Ic drugs than during conventional treatment (4.9 versus 45.6, $p<0.001$) in a population of patients with the following criteria: (2+)

- age 18 to 75
- left ventricular ejection fraction (LVEF) greater than 50%
- no history of severe heart disease
- systolic blood pressure (BP) greater than 100 mmHg
- heart rate greater than 70 bpm.

Another study found a similar result using similar selection criteria among patients with paroxysmal SVT.[191] (2+)

8.2.3 From evidence to recommendations

The limited evidence suggested that pill-in-the-pocket treatment was associated with a lower incidence of inpatient and emergency hospital admissions than conventional treatment.[190,191] It was uncertain whether the pill-in-the-pocket strategy was associated with more adverse events, or reduced episode duration when compared to in-hospital treatment.

Within the UK, the number of patients managed in this way is currently thought to be small, and patients need to be made more aware of this treatment option, although strict selection

criteria are deemed necessary. In particular, it was considered that patient education in its use is vital.

Therapy for paroxysmal AF should be tailored to the patient. For example, episodes of AF for 1 to 2 minutes once a year or for 10 hours twice a day are both paroxysmal AF, but their impact on the patient's quality of life, if symptomatic, would be quite different. In patients with infrequent and brief paroxysms, the regular use of antiarrhythmic therapy may not be necessary (and is commonly not prescribed in current clinical practice). Such patients may be suitable for the pill-in-the-pocket approach. However, for infrequent but protracted and symptomatic paroxysmal AF, rapid cardioversion of each event and/or antiarrhythmic drug prophylaxis may be considered.

RECOMMENDATION

R33 In patients with paroxysmal AF, a pill-in-the-pocket strategy should be considered in those who:

- have no history of left ventricular dysfunction, or valvular or ischaemic heart disease; and
- have a history of infrequent symptomatic episodes of paroxysmal AF; and
- have a systolic blood pressure greater than 100 mm Hg and a resting heart rate above 70 bpm; and
- are able to understand how to, and when to, take the medication. **C**

8.3 Antithrombotic therapy for paroxysmal AF

Patients with paroxysmal AF appear to carry the same risk of stroke and thromboembolism as those with persistent AF.[192] Whether the risk is dependent upon the frequency of the paroxysms or their duration is unclear.[193] In addition, patients frequently get asymptomatic paroxysms[31] and may still be at risk of thromboembolism. There is evidence of some clustering of thromboembolic events around the time of onset of AF[167,194] and following successful cardioversion.[139] Compared with permanent AF, patients with paroxysmal AF tend to be younger[18] and have a lower prevalence of associated clinical risk factors.

8.3.1 Methodological introduction

No studies were found that considered the efficacy of antithrombotic therapy compared with placebo in a population comprising only paroxysmal AF patients.

However, subgroups of patients with paroxysmal AF were reported in two meta-analyses. One meta-analysis[192] pooled data from the aspirin treatment arms of three serial trials and compared ischaemic stroke rates in the paroxysmal AF subgroup with those of non-paroxysmal AF patients. The second study[174] compared the effects of anticoagulation and antiplatelet therapy on rates of ischaemic stroke and major bleeding in a subgroup of participants with paroxysmal AF.

8.3.2 Evidence statements

One meta-analysis[174] found that in patients treated with aspirin, the incidence of stroke was similar in those with paroxysmal AF and those with non-paroxysmal AF. (**2++**)

One meta-analysis[192] found adjusted-dose warfarin to be associated with a reduced incidence of ischaemic stroke compared with aspirin (1.5% versus 4.7%, respectively, $p<0.05$), although no significant difference was found in terms of the incidence of bleeding events. The study also found the efficacy of warfarin in reducing the incidence of stroke to be comparable between those with paroxysmal and those with non-paroxysmal AF. (**1+**)

8.3.3 From evidence to recommendations

The data from clinical trials were limited by the relatively small number of patients with paroxysmal AF (approximately 12% of subjects in five randomised trials).[192] There was some evidence that patients with paroxysmal AF receiving aspirin experience a similar rate of ischaemic stroke as patients with non-paroxysmal AF who receive aspirin.[192]

The effectiveness of anticoagulation compared with antiplatelet therapy in reducing the rate of ischaemic stroke is similar for patients with either paroxysmal AF or non-paroxysmal AF.[174] The rate of adverse bleeding events associated with anticoagulation is also similar between the two groups.[174]

In current clinical practice, the indicators for antithrombotic therapy are highly variable (often depending on the clinical presentation of symptoms). For example, the more frequent a patient's paroxysms the more likely they will be prescribed anticoagulants, despite the risk of stroke being determined by the presence of associated risk factors. It was concluded that patients with paroxysmal AF required a similar degree of anticoagulation as patients with permanent AF, but that further studies would be required to confirm this.

RECOMMENDATION

R34 Decisions on the need for antithrombotic therapy in patients with paroxysmal AF should not be based on the frequency or duration of paroxysms (symptomatic or asymptomatic) but on appropriate risk stratification, as for permanent AF (see section 11.6). **B**

8.4 Rhythm-control treatment algorithm for paroxysmal AF

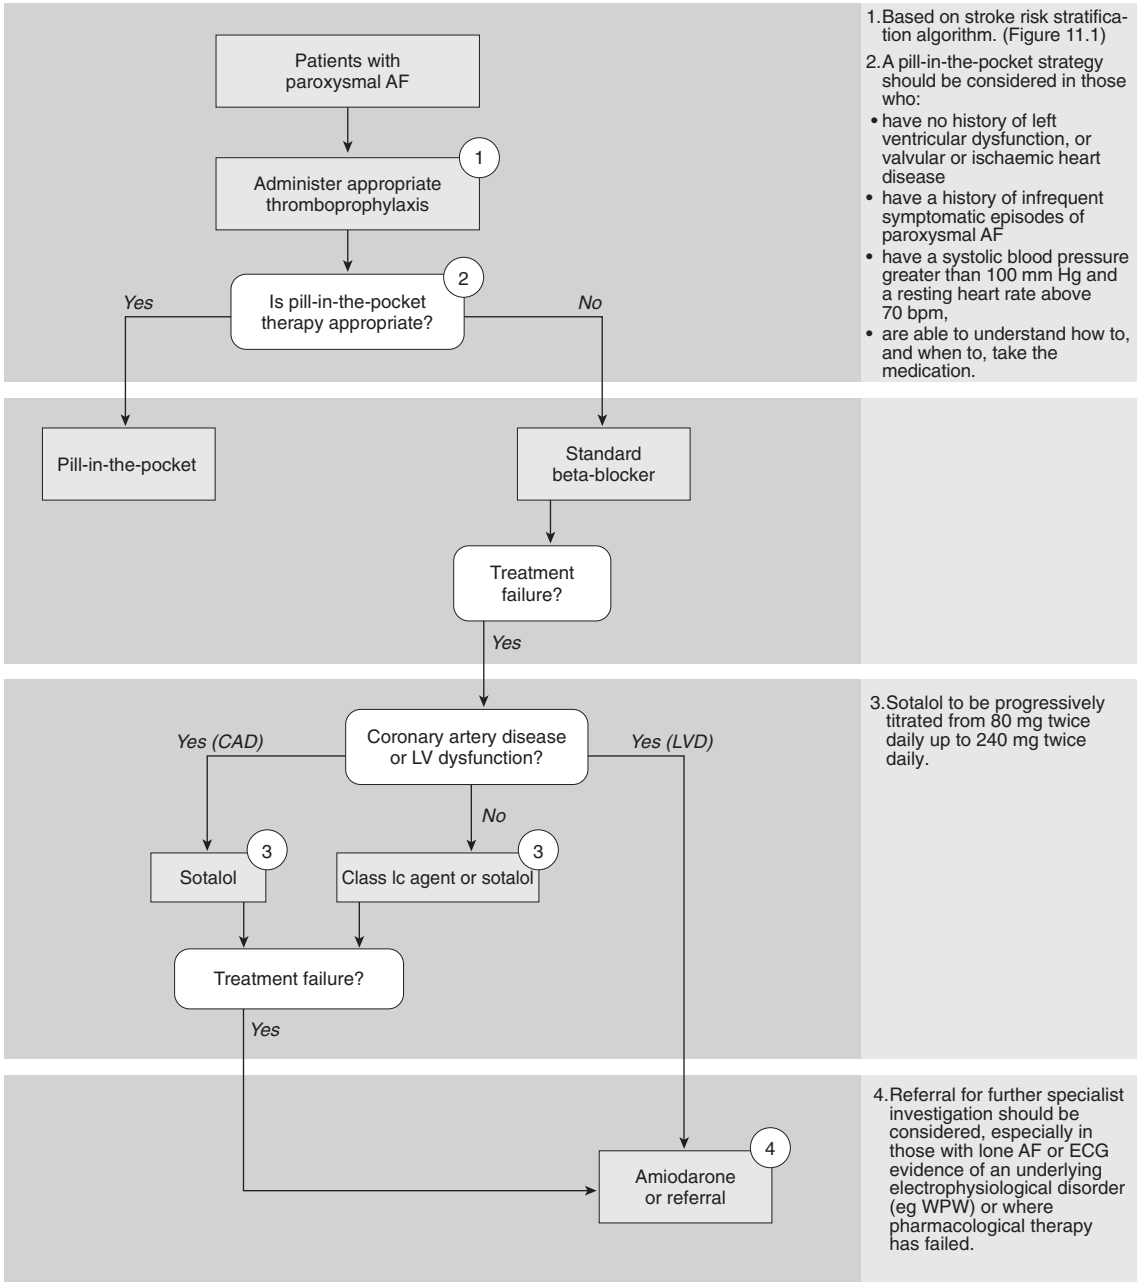

Figure 8.1 Rhythm-control treatment algorithm for paroxysmal AF

9 Treatment for acute-onset AF

9.1 Acute AF in haemodynamically unstable patients

Although most patients in AF present without haemodynamic compromise, there is a small group of patients who are significantly compromised by the onset of AF. These patients require immediate hospitalisation and urgent intervention to prevent further deterioration.

Those considered at highest risk from haemodynamic instability caused by AF have been defined as:[195]

- those with a ventricular rate greater than 150 bpm
- ongoing chest pain, or
- critical perfusion.

In these circumstances, the concerns regarding intervention in the absence of anticoagulation and echocardiography are counterbalanced by the need for urgent treatment. This may include the need to treat important problems such as hypoxia, left ventricular failure, acute ischaemia, pyrexia and electrolyte disorders.

A number of specific issues are recognised in current UK practice for the management of patients with AF in the presence of haemodynamic instability:[65]

- The slow onset of digoxin makes it inappropriate for use in this situation.
- Patients whose AF is associated with thyrotoxicosis will not respond to any strategy that does not first treat the underlying thyroid disease.
- Patients with an accessory pathway such as Wolff–Parkinson–White (WPW) syndrome are particularly at risk following the onset of AF because they can present with high ventricular rates (greater than 200 bpm) and may need specific management.

Treatment with AV node blockers (eg adenosine, digoxin, verapamil, diltiazem) will unmask or exacerbate a rapid AF due to a WPW syndrome and are therefore contraindicated in such patients.[196]

In patients with AF associated with an unacceptably high ventricular rate the primary aim is one of rate control. In other patients with acceptable ventricular rates whose cardiac function has been compromised by AF onset in the context of other cardiac abnormalities (eg hypertensive heart disease, valvular heart disease), rate control is unlikely to bring about clinical improvement and there is a need for the restoration of sinus rhythm.

In clinical practice, amiodarone is the most common agent used in the management of patients presenting in AF with haemodynamic compromise, as it appears to have a hybrid effect of rapid reduction in ventricular rate in most patients with a proportion of these reverting to sinus rhythm over a longer period. An alternative choice suitable for use in patients with invasive monitoring is esmolol, which is an intravenous beta-blocker with a short half-life, which allows for accurate and frequent titration.

9.1.1 Methodological introduction

No studies were found that made a direct comparison between different treatment strategies in haemodynamically unstable patients. However, one observational study[26] was found reporting outcomes between different emergency interventions for AF. This study was in a mixed population including haemodynamically stable patients, and excluded those in whom immediate electrical cardioversion (ECV) or intubation was indicated on the basis of severe haemodynamic instability or respiratory failure. Nonetheless, the mean ventricular rate reported in this study did suggest the presence of rapid AF in a substantial proportion of the included patients.

In addition, three other studies were found reporting the effectiveness of either diltiazem in the acute control of ventricular rate[197] or amiodarone for acute pharmacological cardioversion[112,198] in patients with rapid AF.

Only one study[198] was found in the context of severe haemodynamic instability, occurring in an intensive-care setting in ventilated patients with severely impaired left ventricular dysfunction.

No studies were found reporting the effectiveness of ECV in the successful treatment of AF in the context of haemodynamic instability, although one study[26] did report the effectiveness of ECV in a population consisting primarily of acute-onset AF patients with a fast ventricular rate and a previous attempt at pharmacological cardioversion (PCV).

Studies that considered head-to-head drug comparisons for either ventricular rate-control or PCV are not considered here. For a comparison of drugs for use in PCV, see section 5.2 above; for use in ventricular rate control see section 7.1 above.

9.1.2 Evidence statements

One observational study[26] found that ECV successfully restored sinus rhythm in 89% of patients presenting with acute-onset AF and a mean ventricular rate of 122 bpm. Eighty-three per cent were refractory to an earlier attempt at pharmacological cardioversion using procainamide (which was successful in 50% of cases at doses between 500 and 1000 mg and had an incidence of adverse events of 9%).[28] The study reported no complications associated with ECV.[28]

Three studies[198–200] found the intravenous administration of amiodarone (eg 5 mg/kg over 5 minutes) to be an effective treatment for the restoration of sinus rhythm in patients with varying degrees of haemodynamic instability, including a group of intubated patients with severely impaired cardiac function.[28,198] However, one study[199] found an increased risk of bradycardia following amiodarone in those presenting with a slower initial heart rate. (2+)

One study[26] found the administration of rate-controlling drugs (beta-blockers, rate-limiting calcium antagonists or digoxin) to be an effective strategy to reduce ventricular rate in 75% of AF patients with a fast ventricular rate.[28] A similar result was reported in another study[197] with the rate-limiting calcium antagonist diltiazem.[28]

Two studies[198,200] found the intravenous administration of amiodarone (5 mg/kg over 3 to 5 minutes[200] or 300 mg bolus via central line[198]) to be an effective strategy to control ventricular rate in haemodynamically impaired patients.[28]

9.1.3 From evidence to recommendations

Based on limited available evidence, pharmacological rate-control and both pharmacological and electrical cardioversion are effective treatment options for the acute management of patients presenting with various degrees of haemodynamic instability.

In UK clinical practice, very sick patients with fast AF and haemodynamic compromise were often inappropriately administered iv flecainide. Flecainide should not be used in such patients unless they are known to have rapid AF consequent upon a WPW syndrome.

It was noted that the use of AV node blockers would unmask or exacerbate a rapid AF due to a WPW syndrome and their use is contraindicated in these patients. Digoxin was less effective in haemodynamically compromised patients due to its slow onset of action and possible adrenergic activity.

Intravenous amiodarone is widely used as it both rapidly reduces ventricular heart rate and cardioverts AF. In an emergency setting, amiodarone is likely to be administered intravenously via a peripheral line.

RECOMMENDATIONS

R35 In patients with a life-threatening deterioration in haemodynamic stability following the onset of AF, emergency electrical cardioversion should be performed, irrespective of the duration of the AF. **D**

R36 In patients with non life-threatening haemodynamic instability following the onset of AF:

- electrical cardioversion should be performed **D**
- where there is a delay in organising electrical cardioversion, intravenous amiodarone should be used **D**
- in those with known Wolff–Parkinson–White syndrome:
  - flecainide may be used as an alternative for attempting pharmacological cardioversion
  - atrioventricular node-blocking agents (such as diltiazem, verapamil or digoxin) should not be used. **D(GPP)**

R37 In patients with known permanent AF where haemodynamic instability is caused mainly by a poorly controlled ventricular rate, a pharmacological rate-control strategy should be used. **D**

R38 Where urgent pharmacological rate-control is indicated, intravenous treatment should be with one of the following:

- beta-blockers or rate-limiting calcium antagonists **D**
- amiodarone, where beta-blockers or calcium antagonists are contraindicated or ineffective. **D**

9.2 Antithrombotic therapy for acute-onset AF

The aim of this section is to examine which antithrombotic therapy, if any, is most effective in treating patients with acute-onset AF, including the postoperative setting.

The onset of AF is associated with a cluster of thromboembolic events,[167] but the development of intra-atrial thrombi, and the immediate risk of thromboembolism, is perceived to be minimal within the first 48 hours.

In one study of 357 patients with symptomatic acute-onset AF of less than 48 hour duration (of whom 250 converted spontaneously to sinus rhythm and 107 underwent cardioversion without any anticoagulation), thromboembolism only occurred in three patients.[140] In another series of 258 patients undergoing cardioversion for AF of less than 2 days duration, only one embolic event occurred out of 198 patients who did not receive pre- or post-cardioversion warfarin.[143] However, in a further study, patients with acute AF of an apparent duration of less than 3 days were found to have an intra-atrial thrombus detected by TOE in approximately 15% of cases.[201] This raises the possibilities that either the development of intra-atrial thrombus may be more rapid than previously suspected and/or that some cases of presumed recent-onset AF may have had the arrhythmia (possibly asymptomatically) for longer.

Thus, in patients presenting *de novo* with AF, a clear history of arrhythmia onset is necessary in order to guide appropriate antithrombotic therapy and, if performed, the safety of cardioversion.

9.2.1 Methodological introduction

No studies were found that addressed this clinical area.

9.2.2 From evidence to recommendations

Although no randomised trials have specifically addressed the issue of acute-onset AF, common clinical practice indicates that cardioversion may be safely performed without the need for oral anticoagulation if AF has been present for less than 48 hours.[202] However, in cases of uncertainty about arrhythmia onset, anticoagulation therapy is warranted.

The GDG discussed the use of intravenous unfractionated heparin and subcutaneous low molecular weight heparin (LMWH). Both drugs are routinely used in clinical practice in the acute and peri-cardioversion periods. It was agreed that anticoagulation with heparin could be started at the presentation of acute AF while the INR remains subtherapeutic during the initiating phase of oral anticoagulation.

Acute AF may present with a fast ventricular response, leading to haemodynamic instability, which may require urgent direct current (DC) cardioversion. Where the degree of haemodynamic instability is life threatening (for example, cardiogenic shock), DC cardioversion may need to be performed rapidly and in such cases would take priority over the need for anticoagulation.

RECOMMENDATIONS

R39 In patients with acute AF who are receiving no, or subtherapeutic, anticoagulation therapy: **D(GPP)**

- in the absence of contraindications, heparin should be started at initial presentation
- heparin should be continued until a full assessment has been made and appropriate antithrombotic therapy has been started, based on risk stratification (see section 11.6).

R40 In patients with a confirmed diagnosis of acute AF of recent onset (less than 48 hours since onset), oral anticoagulation should be used if:

- stable sinus rhythm is not successfully restored within the same 48-hour period following onset of acute AF, or
- there are factors indicating a high risk of AF recurrence,* or
- it is recommended by the stroke risk stratification algorithm (see Figure 11.1). **D(GPP)**

R41 In patients with acute AF where there is uncertainty over the precise time since onset, oral anticoagulation should be used, as for persistent AF (see section 6.2). **D(GPP)**

R42 In cases of acute AF where the patient is haemodynamically unstable, any emergency intervention should be performed as soon as possible and the initiation of anticoagulation should not delay any emergency intervention. **D(GPP)**

*Factors indicating a high risk of AF recurrence include:

- a history of failed attempts at cardioversion
- structural heart disease (mitral valve disease, left ventricular dysfunction or an enlarged left atrium)
- a prolonged history of AF (greater than 12 months)
- previous recurrences of AF.

9.3 Haemodynamically unstable AF treatment algorithm

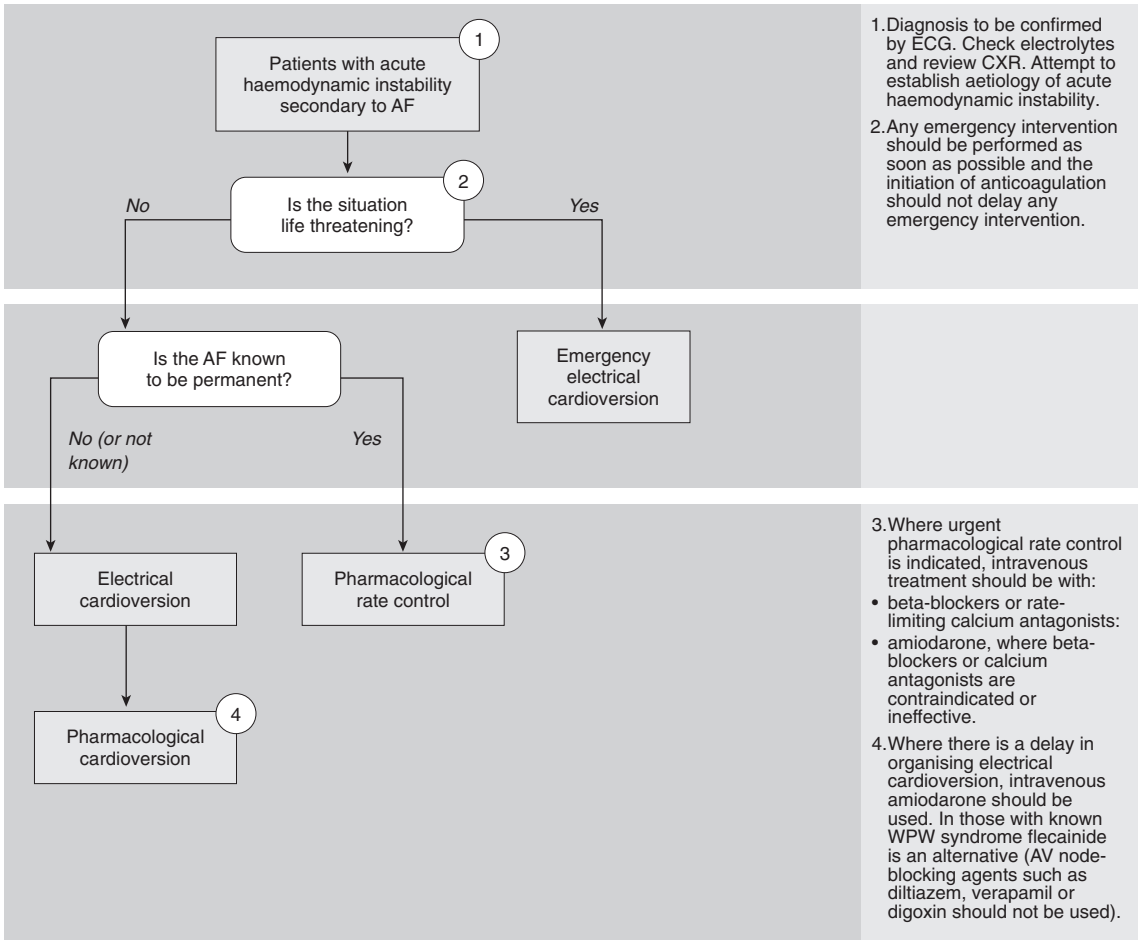

Figure 9.1 Haemodynamically unstable AF treatment algorithm

10 Postoperative AF

Postoperative AF (post-op AF) following cardiothoracic surgery is a significant problem, occurring in approximately 33% of patients after coronary heart surgery.[203] The occurrence following valvular heart surgery is even higher.[204]

Post-op AF is associated with a greater risk of mortality and morbidity.[205] Evidence is also emerging[206] that post-op AF predisposes people to a significantly increased risk of stroke and thromboembolism, suggesting that patients should be anticoagulated where post-op AF persists for more than 48 hours.[207]

Although post-op AF can be transient and generally self-limiting, treatment is indicated for those patients who remain symptomatic, become haemodynamically unstable, and develop cardiac ischaemia or heart failure. Conventional treatment strategies have included ECV, atrial overdrive pacing using temporary epicardial pacing leads (if atrial flutter is the dominant rhythm), pharmacological rate control and antithrombotic therapy. Cardioversion may also be attempted prior to hospital discharge.

Management of medical comorbidities (eg hypoxia) and the correction of underlying electrolyte imbalance (especially potassium and magnesium) is well recognised[208,209] in the prevention of post-op AF. Most units have strategies to maintain the serum potassium above 4 mmol per litre and some will often endeavour to maintain the serum potassium higher than 4.5 mmol per litre.[210] One recent meta-analysis[211] found that magnesium administration is an effective prophylactic measure for the prevention of post-op AF, but did not significantly alter length of stay or in-hospital mortality.

Currently, there is significant variation in the management of post-op AF. The aim of this chapter is to assess whether the perioperative administration of antiarrhythmic drugs is effective prophylaxis to prevent post-op AF (section 10.1), and in those cases where post-op AF develops, to determine which is the most effective treatment strategy (section 10.2).

10.1 Drug prophylaxis for postoperative AF

10.1.1 Methodological introduction

Of the studies considering prophylaxis, the majority concerned the prevention of post-op AF following cardiac surgery, and most of these results are summarised in a meta-analysis.[212] The other studies[213–218] considered non-cardiac thoracic procedures (eg pneumonectomy).

The reporting of side effects associated with antiarrhythmic drugs was not consistent, with many studies having too few participants to make any meaningful comparisons.

Studies were included if comparison was made between an antiarrhythmic drug or cardiac glycoside available in the UK, and a placebo or no-treatment control. The management of electrolyte imbalance (eg magnesium or potassium) was not assessed.

Five US studies[218,219–222] considering the cost-effectiveness of drug prophylaxis were appraised and met quality criteria.

- Two studies[219,220] estimated the mean cost per case of post-op AF avoided, of oral amiodarone prophylaxis versus no prophylaxis in patients undergoing coronary bypass grafting (CABG).
- One study[221] estimated the cost per AF averted of intravenous amiodarone therapy in CABG, valve and CABG plus valve patients, according to their predicted risk of postoperative AF.
- One study[218] estimated the median total hospital costs in patients with and without oral amiodarone prophylaxis based on the medical records of patients after pulmonary resection.
- One study[222] estimated the total hospitalisation costs in a RCT of oral amiodarone prophylaxis versus placebo in patients undergoing cardiopulmonary bypass.
- One study[219] estimated the total hospital costs in oral amiodarone prophylaxis versus placebo groups based on the Atrial Fibrillation Suppression Trial.

10.1.2 Evidence statements

▷ Drug prophylaxis in cardiac surgery

Amiodarone

In a meta-analysis of 14 studies[212] which compared amiodarone with placebo or no treatment, amiodarone administered pre-, intra- or postoperatively was found to be associated with a reduced incidence of post-op AF or other supraventricular arrhythmia (OR 0.54, 95% CI 0.44 to 0.67; p<0.00001) (**1+**). Similar results were found in other primary studies.[223–230] (**1++**)

In one study[231] amiodarone was significantly associated with a reduced incidence of post-op AF lasting longer than 24 hours, and episodes that required treatment, compared with placebo. (**1++**)

One study[224] found that amiodarone resulted in a reduced duration of post-op AF compared with no treatment (11.0 versus 16.2 days; p<0.001) (**2+**). Two smaller studies[222,232] found no significant difference in the duration of post-op AF. (**1++**)

One study[231] found rapid preoperative amiodarone loading resulted in more nausea than placebo (31.3% versus 16.0%; p=0.018), this was not observed with slow loading (21.4% versus 16.0%) (**1++**). There was no difference reported in the incidence of hypotension for either strategy. (**1++**)

Beta-blockers (excluding sotalol)

One meta-analysis of 28 studies[212] found beta-blockers (excluding sotalol) resulted in less post-op AF and other supraventricular arrhythmias (OR 0.35, 95% CI 0.26 to 0.49; p<0.00001) (**1+**). This result is consistent with the results of other primary studies,[226,230,233–235] in one of which[226] there was a significant increase in postoperative symptomatic bradycardia (less than 40 bpm) compared with placebo (16.1% versus 3.1%; p<0.05). (**1+**)

Sotalol

A meta-analysis of eight studies[212] found sotalol reduced post-op AF and other supraventricular arrhythmias compared with control (OR 0.36, 95% CI 0.23 to 0.56) (**1+**). Two other primary

studies[226,236] showed similar results, one of which[226] found a significant association between the use of sotalol (240 mg three times a day) and the incidence of postoperative symptomatic bradycardia (<40 bpm) compared with placebo (12.7% versus 3.1%; p<0.05) (**1+**). The study did not report any incidence of pro-arrhythmic side effects associated with sotalol.

Rate-limiting calcium antagonists

Four studies[237–240] found the rate-limiting calcium antagonist diltiazem to be significantly associated with a lower incidence of post-op AF compared with placebo or no treatment (**1++**). A similar result has also been found for the rate-limiting calcium antagonist verapamil.[241] (**1+**)

Propafenone

One study[242] found propafenone administered at 675 mg/day (although not at 450 mg/day) decreased post-op AF compared with placebo. (**1++**)

Procainamide

One study[243] found no difference in the incidence of post-op AF between procainamide and placebo but did reduce the number of patient days spent in post-op AF (16 versus 19 days; p<0.05) (**1++**). It was found to be significantly associated with an increased incidence of nausea compared with placebo (64% versus 32%; p<0.01) (**1++**). Another smaller study[244] (N=46) found procainamide to be significantly associated with a reduced incidence of post-op AF compared with placebo (3.9% versus 10.6%; p<0.04). (**1++**)

Digoxin

A meta-analysis of two studies,[235] as well as another primary study[245] not included in the meta-analysis found digoxin did not reduce post-op AF when compared with no treatment. (**1+**)

▷ Drug prophylaxis in thoracic (non-cardiac) surgery

Beta-blockers

One study[246] found beta-blockers to be effective in reducing post-op AF compared with placebo in favour of beta-blockers (6.7% versus 40.0%; p<0.05) (**1+**). Another[217] found a non-significant reduction in any arrhythmia requiring treatment but increased incidences of post-operative bradycardia and hypotension respectively (25% versus 4% compared with placebo; p=0.018; 49% versus 26% compared with placebo; p=0.003). (**1++**)

Rate-limiting calcium antagonists

One study[213] found diltiazem did not significantly reduce the overall incidence of post-op AF; but when considering those over 60 years old only (15% versus 25%; p=0.05), or when other cardiac arrhythmias were included (14% versus 26%; p=0.03), diltiazem was effective (**1++**). Another study[214] did not find diltiazem effective compared with placebo (8% versus 15%). (**1+**)

Flecainide

One study[215] found flecainide effectively reduced all postoperative cardiac arrhythmia requiring treatment (including AF) compared with placebo (0% versus 6%; p<0.05). (**1++**)

Digoxin

One study[216] found no other treatments compared with digoxin in reducing the incidence of post-op AF following pneumonectomy (31% versus 28%). (**2+**)

Amiodarone

One study[218] found amiodarone reduced post-op AF compared with no treatment (9.7% versus 33%; p=0.025) following pneumonectomy. (**2+**)

Health economics

There was no significant difference in total hospital costs in oral amiodarone prophylaxis versus placebo (US$15,565 + US$9,832 versus US$16,126 + US$8,043, p=0.12) and a higher percent of episodes of AF prevented (77% versus 62%).[219]

There was no significant difference between median total hospital costs (US$30,800 (20,400–96,900) in 50 patients without prophylaxis versus US$26,700 (11,000–55,900) in 31 patients with low dose oral amiodarone prophylaxis). Significantly less patients developed postoperative AF with low dose oral amiodarone (9.7% versus 33%, p=0.0253).[218]

One study[222] found a significantly lower mean total cost of hospitalisation in the oral amiodarone group compared with placebo in patients undergoing cardiopulmonary bypass surgery (US$18, 375 + US$13,863 versus US$26,491 + US$23,837, p=0.03).

One study[219,220] estimated the mean cost per AF event avoided was lower in the oral amiodarone group versus no prophylaxis (US$15,750, 95% CI US$15,591 to US$15,999 versus US$17,426, 95% CI US$17,252 to US$17,600). Multivariate sensitivity analysis indicated these findings were most sensitive to the cost of hospitalisation and frequency of AF.

One study[221] indicated the cost effectiveness of prophylactic intravenous amiodarone therapy varied according to the type of cardiac surgery and predicted risk of postoperative AF. As the risk of AF in the targeted patients increases, the cost-effectiveness ratio improves.

- For CABG patients, the ICERs ranged from US$10,938 for the highest risk patients to US$55,854 per AF averted in the lowest risk patients.
- For valve replacement patients the ICERs ranged from US$4,219 in the highest risk patients to US$43,011 per AF averted in the lowest risk patients.
- For CABG and valve replacement patients the ICERs ranged from US$69 for the highest risk patients to US$39,698 per AF averted in the lowest risk patients.

10.1.3 From evidence to recommendations

Although no specific evidence was evaluated regarding the association between electrolyte balance and the incidence of post-op AF, it was agreed that scrupulous attention to electrolyte balance was important.

Drug prophylaxis to reduce the risk of post-op AF relates to the need to:

- continue existing medication (eg beta-blockers)
- administer a drug preoperatively (eg beta-blockers or amiodarone), or
- administer a drug in the immediate postoperative period (eg sotalol or amiodarone).

In many of the studies, the majority of patients were already taking beta-blockers pre-operatively, and these were either discontinued in the postoperative period or continued, despite the use of beta-blockers being recognised as an independent (negative) predictor of post-op AF.[247,248] In those studies where beta-blockers were continued postoperatively, the results may be confounded by this additional cardioprotective effect, which may be insensitive to additional antiarrhythmic medication, particularly beta-blockers, thus underestimating the effectiveness of the prophylaxis.

Alternatively, in those studies where beta-blockers were discontinued, the incidence of post-op AF may be exaggerated by the withdrawal of the cardioprotective effects of beta-blockers, which in some patients may have been preventing the development of arrhythmias aetiologically independent from post-op AF.

For non-cardiac thoracic surgery, there was evidence for efficacy of the same drugs as used in cardiac surgery in the prevention of post-op AF.

It was agreed that beta-blockers, including sotalol, were effective prophylactic drugs, and that those patients who were receiving pre-existing therapy with these drugs would benefit from a reduced risk of post-op AF if those drugs were continued, unless there were compelling reasons to withdraw them (eg postoperative hypotension or bradycardia).

It was agreed that digoxin is not effective in preventing postoperative AF.[235,245]

Administering amiodarone slowly over 5 to 7 days preoperatively and continuing during the perioperative period is more effective and associated with fewer side effects than more rapid loading.[231]

There is an increased risk of bradycardia associated with the use of beta-blockers and nausea associated with procainamide, as well as with amiodarone when loaded rapidly in the pre-operative period.

Data from the USA suggest the prophylactic administration of amiodarone for the prevention of post-op AF is cost effective, particularly in high-risk patients, compared with no prophylaxis for certain cardiac procedures. It was noted that there may be cost differentials between the UK and the USA for antiarrhythmic drugs.

RECOMMENDATIONS

R43 In the prophylaxis and management of postoperative AF, the appropriate use of antithrombotic therapy and correction of identifiable precipitants (such as electrolyte imbalance or hypoxia) is recommended. **D(GPP)**

R44 In patients undergoing cardiothoracic surgery:

- the risk of postoperative AF should be reduced by the administration of one of the following:
  - amiodarone **A**
  - a beta-blocker **A**
  - sotalol **A**
  - a rate-limiting calcium antagonist **B**
- digoxin should not be used. **B**

R45 In patients undergoing cardiac surgery on pre-existing beta-blocker therapy, this treatment should be continued unless contraindications develop (such as postoperative bradycardia or hypotension). **A**

10.2 Treatment for postoperative AF

10.2.1 Methodological introduction

The results of nine studies considering the treatment of postoperative AF were included, all except one[249] were prospective RCTs. The other was placebo-controlled[250] with a 2 × 2 crossover study design with no reported wash-out period between crossover. Of the reported RCTs, none had the statistical power to identify effect sizes that may be considered clinically significant.

A rate-control strategy was defined as one which involved the administration of drugs to control heart rate; a rhythm-control strategy was defined as one which involved treatment with electrical or pharmacological cardioversion or the administration of drugs known to be effective in pharmacological cardioversion. In many studies the objectives of each treatment group were not explicitly reported, in which case a comparison of a rate-control treatment strategy with a rhythm-control treatment strategy was presumed based on the established differential actions of the interventions considered. The duration of follow-up times varied between the studies (less than 1 hour to 30 days).

One study[250] compared rhythm control to no-treatment. All of the other studies compared rate control with pharmacological rhythm control. There were no studies comparing either rate control with rhythm control using electrical cardioversion or rate control versus no treatment.

None of the studies reported results for patients with post-op AF and haemodynamic instability requiring urgent medical intervention.

10.2.2 Evidence statements

In patients with post-op AF, where various rhythm- and rate-control strategies have been compared (see Tables 10.1 and 10.2), rhythm control results in:

- greater cardioversion within 1 hour but not after 24 hours[250–255]
- shorter time for restoration of sinus rhythm[256]
- no difference in ventricular rate control[250,255]
- higher rates of therapeutic effectiveness[255]
- no difference in relapse rates.[256]

Table 10.1 Comparison of rhythm-control treatments for post-op AF with rate-controlling treatments or no treatment in terms of percentage of patients reverting to sinus rhythm

	Comparison	N	Period (hours)	Rhythm (%)	Control (%)	p
(1+)	Flecainide/digoxin[255]	29	1	60	0	<0.001
(1+)	Propafenone/placebo[250]	14	1	43	0	<0.001

(1+)	AF recurrence at 8 weeks	50	Rhythm-control drugs/ rate-control drugs*[256]	4%	9%	NS
(1+)	AF recurrence	40	Sotalol/digoxin†[253]	5%	35%	<0.05

*Rhythm-control drugs: sotalol, procainamide, propafenone or amiodarone.
Rate-control drugs: diltiazem, verapamil, beta-blockers or digoxin.
**HR <100 bpm within 45 minutes of administration.
†Digoxin with additional disopyramide if sinus rhythm was not restored within 2 hours.

Two studies[249,256] of various rhythm-control versus rate-control strategies have shown shorter overall length of hospital stay with rhythm-control strategies but results for postoperative length of stay have been inconsistent (see Table 10.3).

Table 10.3 Comparison of rhythm-control and rate-control treatments in terms of length of stay (days)

	Study	N	LOS measure	Rhythm	Rate	p
(1+)	Lee *et al*[256]	50	Hospital	9.0	13.2	<0.05
(1+)	Lee *et al*[256]	50	Post-op only	7.4	9.7	<0.01
(2+)	Shah *et al*[249]	101	Post-op only	8.3	6.3	<0.01

LOS measure = length of hospital stay measure.

10.2.3 From evidence to recommendations

The GDG agreed that the evidence suggested a trend towards a strategy of rhythm control over rate control. The evidence suggested that rhythm control produced a decreased time to cardioversion, prolonged maintenance of cardioversion, and decreased length of overall hospital stay.[256]

However, the data supported the use of a rhythm-control strategy in achieving sinus rhythm only in the short term. In the longer term, there is little difference in the maintenance of sinus rhythm between either strategy.[250–255] It was noted that the number of study participants was relatively small and the follow-up periods were relatively short. Overall, it was concluded that a rhythm-control strategy provided short-term benefits.

RECOMMENDATIONS

R46 Unless contraindicated, a rhythm-control strategy should be the initial management option for the treatment of postoperative AF following cardiothoracic surgery. **C**

R47 Unless contraindicated, postoperative AF following non-cardiothoracic surgery should be managed as for acute-onset AF with any other precipitant. **D(GPP)**

11 Antithrombotic therapy

11.1 Initiating antithrombotic therapy

AF is an independent predictor of stroke, with an annual risk that is 5 to 6 times higher than patients in sinus rhythm. However, this risk is not homogeneous, ranging from an annual risk of 1% in patients aged over 65 years old with no risk factors, to over 12% per year in patients who have a history of prior stroke, transient ischaemic attack or thromboembolism. Not only is AF a major risk factor for stroke, but when strokes occur in association with AF, the patients suffer substantial mortality, morbidity, disability and longer hospital stays compared with stroke patients without AF.

The benefits of thromboprophylaxis in patients with AF are well established in randomised trials, and most guidelines recommend the use of anticoagulation with warfarin for high-risk patients. However, there continues to be wide variation in management. In particular, the elderly are at the highest risk of stroke, and would benefit most from thromboprophylaxis. However, the elderly have more comorbidities and concomitant therapies that may preclude anticoagulant therapy. Also, most of the evidence on thromboprophylaxis has been based on hospital-managed populations and the application to primary care management and anticoagulation monitoring is still uncertain.

Common practice upon detection or initial presentation of a patient with AF in the community or when an AF patient presents to a non-specialist is to refer to a specialist clinic to decide on appropriate antithrombotic therapy. For example, in a survey of accident and emergency consultants in the UK, many were reluctant to make a decision regarding anticoagulation, and preferred referral to a medical or cardiology team.[257]

This may lead to delays in the institution of appropriate thromboprophylaxis, and may increase a patient's risk of stroke or thromboembolism. However, risk stratification for thromboprophylaxis can be easily performed on clinical criteria (see section 11.6).

Evidence-based guidance is required to determine whether it is beneficial to start antithrombotic therapy immediately following the initial diagnosis of AF, rather then delay initiation, pending assessment at a specialist clinic.

11.1.1 Methodological introduction

The literature search and evidence appraisal processes for this question resulted in no studies suitable for appraisal.

11.1.2 From evidence to recommendations

Although there was no appraisable evidence base, the issue of early versus delayed administration of anticoagulation in acute patients newly diagnosed with AF was considered of great importance. It was agreed that the administration of anticoagulation after treating comorbidities (eg hypertension) was good clinical practice.

RECOMMENDATION

R48 In patients with newly diagnosed AF for whom antithrombotic therapy is indicated (see section 11.6), such treatment should be initiated with minimal delay after the appropriate management of comorbidities. **D(GPP)**

11.2 Antithrombotic therapy in acute stroke patients*

Approximately a third of patients presenting with an acute stroke are found to have AF. These patients have high mortality and morbidity. Prior to the administration of antithrombotic therapy, intracranial haemorrhage needs to be excluded, and an assessment of the risk from haemorrhagic transformation in patients with large cerebral infarcts needs to be made. While warfarin is superior to aspirin for the secondary prevention of stroke in AF,[258] there is uncertainty about the optimal timing of administration of anticoagulants following acute stroke. The presumption is that most of these patients have cardiogenic embolism, from intracardiac thrombi, but many patients with AF can also develop lacunar strokes secondary to hypertension and other comorbidities and in such cases warfarin is less effective.[259]

The mortality benefits of aspirin therapy following acute stroke[260] are less marked among patients with AF. This may be due to the embolisation of pre-formed intra-atrial thrombus rather than newly formed platelet-thrombus adhering to carotid and cerebral artery atheroma, or may be a reflection of a lesser role of platelets in AF-related stroke.

The purpose of this section is to determine the most appropriate antithrombotic therapy – if any – during the acute post-stroke phase, considering the efficacy of antithrombotic therapies to reduce recurrent stroke, as well as the increased risk of intracranial haemorrhage (ICH) and other major bleeding events.

11.2.1 Methodological introduction

One systematic review[260] considered the results of three primary trials. The trials included peri-stroke patients of varying aetiology. The included studies reported a mean time to treatment of between 19 and 25 hours. Data regarding the subgroup with AF had been published or made available to the authors of the review. All the evidence statements are derived solely from the subgroup comparisons of AF patients.

No trials involving warfarin or any other oral antithrombotic treatment for the prevention of acute recurrent stroke were found.

One of the primary studies included in the systematic review was of a Chinese population.

11.2.2 Evidence statements

In patients with AF the incidence of acute recurrent ischaemic stroke was comparable between treatment with LMWH and aspirin.[260] Another trial found a significant association when

*NICE is developing a clinical guideline on the diagnosis and management of stroke (publication is expected for 2008).

heparin was compared with a no-heparin control group (2% versus 5%; p=0.001) (**1+**). However, the trial also found that the incidence of haemorrhagic stroke was higher in the heparin group (2.8% versus 0.4%), thus offsetting the reduction in ischaemic stroke. (**1+**)

No significant association has been found between the use of aspirin in comparison with either placebo or control and the incidence of acute recurrent stroke (ischaemic or haemorrhagic) or acute mortality (2 to 4 weeks post-stroke).[260] (**1+**)

11.2.3 From evidence to recommendations

It was agreed that there were little data on which to formulate an evidence-based recommendation on when to initiate oral anticoagulation in a patient with AF following a stroke or TIA. In the absence of evidence, it was therefore agreed to base recommendations on pre-existing guidelines in the area.[202]

It was agreed that cerebral imaging may be performed (by MRI or CT scan) to exclude haemorrhage, and antithrombotic therapy should commence at approximatey 2 weeks after the stroke or TIA where there is no evidence of haemorrhage. It should be noted, however, that the discrimination between haemorrhage and ischaemic stroke with CT scanning can only be made reliably within a few days of the event. At later times gradient echo MRI may be the only reliable method.

In patients with AF who have had a large infarction or uncontrolled hypertension, antithrombotic therapy may be delayed. Although AF is widely recognised as a significant risk factor for ischaemic stroke, patients with AF may have other risk factors. AF may not be responsible for all strokes occurring in AF patients. Nonetheless, secondary stroke prevention is warranted and AF patients who have experienced an ischaemic stroke will benefit from appropriate antithrombotic therapy according to the recommendations below and the stroke risk stratification algorithm (Figure 11.1) regardless of aetiology.

RECOMMENDATIONS

R49 In all patients with AF who have had an acute stroke, any uncontrolled hypertension should be appropriately managed before antithrombotic therapy is started. **D(GPP)**

R50 In patients with AF and an acute stroke:

- imaging (CT scan or MRI) should be performed to exclude cerebral haemorrhage
- in the absence of haemorrhage, anticoagulation therapy should begin after 2 weeks
- in the presence of haemorrhage, anticoagulation therapy should not be given
- in the presence of a large cerebral infarction, the initiation of anticoagulation therapy should be delayed. **D(GPP)**

R51 In patients with AF and an acute TIA:

- imaging (CT scan or MRI) should be performed to exclude recent cerebral infarction or haemorrhage
- in the absence of cerebral infarction or haemorrhage, anticoagulation therapy should begin as soon as possible. **D(GPP)**

11.3 Antithrombotic therapy following a stroke or TIA

AF is an independent predictor of stroke[13] with the risk approximately five times that of people without AF. The absolute risk for an individual patient, however, increases with age and depends upon the presence of other risk factors such as valvular heart disease, other cardiovascular disease or cardiac risk factors. Conversely, anticoagulation therapy substantially reduces the risk of stroke in 'at risk' patients with AF.[174,260]

In stroke patients, concurrent AF is associated with greater disability, longer in-hospital patient stay and lower rate of discharge to their own home, and in most studies AF is associated with decreased survival.[261,262]

Patients who have suffered and survived an acute stroke or transient ischaemic attack are at the highest risk of recurrent stroke and thromboembolism, approximately 12% per year.[258] Assessment and treatment of comorbidities (especially hypertension) is essential, as is an accurate risk–benefit assessment. The highest risk patients are the elderly, and this is probably the group where anticoagulation treatment is most difficult.

The objective of this section is to provide evidence-based guidelines on which is the best thromboprophylactic agent for post-stroke AF patients.

11.3.1 Methodological introduction

Five primary studies[258,259,263–265] and two meta-analyses[266,267] were identified. One study[258] was included in both meta-analyses. One study compared warfarin, aspirin and placebo.[258] All studies recruited AF patients with a prior stroke or TIA except one[179] that included 44% of AF patients without a prior stroke or TIA.

11.3.2 Evidence statements

One meta-analysis[266] found warfarin to be associated with a reduced incidence of recurrent stroke (ischaemic or haemorrhagic) and vascular events (including stroke, myocardial infarction, systemic embolism and vascular death) but an increased incidence of bleeding events, compared with placebo. (**1+**)

There was no significant difference in the mortality rate between adjusted-dose warfarin and placebo.[258] (**1++**)

Low molecular weight heparin is associated with a significant reduction in embolic events and overall mortality when compared with no treatment.[265] (**1+**)

Acenocoumarol administered to a target INR of 1.25 to 2.00, in conjunction with 600mg/day triflusal, reduces the incidence of stroke (ischaemic or haemorrhagic), vascular death or systemic embolism compared with acenocoumarol alone administered to a target INR of 2.0 to 3.0179 (**1+**). No association has been found in rates of severe bleeding or overall incidence of adverse events.[179] (**1+**)

Adjusted dose warfarin is associated with a reduced incidence of recurrent stroke (ischaemic or haemorrhagic),[258,264] and vascular events[258] compared with aspirin (**1++**). Warfarin has also been found to be associated with an increased incidence of bleeding events compared with aspirin.[258] (**1++**)

No significant difference has been found in the mortality rate between adjusted-dose warfarin and aspirin.[258] (1++)

Warfarin has been found to be associated with a greater reduction in the incidence of overall stroke recurrence following a presumed primary cardioembolic stroke in comparison with aspirin, but not following a presumed primary lacunar stroke.[258] (1++)

No significant difference between aspirin and placebo has been found in the overall incidence of vascular events, mortality or bleeding events.[258] (1++)

No association has been found between the use of dipyridamole and placebo in the incidence of recurrent ischaemic stroke. A similar result was found when dipyridamole was combined with aspirin and compared with placebo.[264] (1++)

11.3.3 From evidence to recommendations

Anticoagulation with warfarin has a strong beneficial effect in the prevention of recurrent strokes for post-stroke and post-TIA patients with AF when compared with both placebo[258,266] and aspirin.[267] This effect is significant for any category of secondary stroke. However, anticoagulation also increases rates of haemorrhagic events in comparison with both placebo and aspirin.

The GDG agreed that antiplatelet agents such as aspirin and dipyridamole are ineffective thromboprophylactic agents and should be administered to post-stroke AF patients only to treat other comorbidities or vascular disease.

The GDG noted that the use of low adjusted-dose anticoagulation with acenocoumarol in combination with the antiplatelet triflusal was more effective than conventional adjusted-dose anticoagulation with acenocoumarol alone for the prevention of stroke.[179] It is unclear whether similar results apply to anticoagulation with warfarin instead of acenocoumarol or other antiplatelet agents. The GDG noted that trifusal is not used in the UK, and that previous studies of warfarin and aspirin combination therapy have been less effective or have had more adverse effects than with warfarin alone. Therefore the GDG did not make any recommendations in this area.

RECOMMENDATIONS

R52 In patients with AF who are either post-stroke, or have had a TIA:

- warfarin should be administered as the most effective thromboprophylactic agent **A**
- aspirin or dipyridamole should not be administered as thromboprophylactic agents unless indicated for the treatment of comorbidities or vascular disease. **D(GPP)**

R53 Treatment of post-stroke or post-TIA patients with warfarin should only begin after treatment of relevant comorbidities (such as hypertension) and assessment of the risk–benefit ratio. **D(GPP)**

11.4 Antithrombotic therapy for asymptomatic AF

Many patients develop AF asymptomatically, and only present to medical care when complications such as stroke or heart failure occur. One study reported that in patients with paroxysmal AF, only 1 in 12 paroxysms appeared to be symptomatic.[31] Consequently, cases of AF are often detected, particularly in the elderly, during a general practice visit for an unrelated problem. The elderly, as a group, have a high morbidity from stroke, thromboembolism and impaired cognitive function.

It is not known whether asymptomatic AF *per se* is a potential risk factor for stroke. It is currently not clear how best to manage patients with asymptomatic AF, either in relation to treatment using a rate-control or a rhythm-control strategy, or in terms of the need for antithrombotic therapy.

11.4.1 Methodological introduction

No studies were found that addressed this clinical area.

11.4.2 From evidence to recommendations

The GDG noted that there was no evidence upon which to base recommendations on the use of antithrombotic therapy in patients with asymptomatic AF. The group noted that many patients had AF diagnosed but that the opportunity for antithrombotic therapy was not always considered. The group agreed that asymptomatic AF should be treated no differently to symptomatic AF.

RECOMMENDATION

R54 Patients with asymptomatic AF should receive thromboprophylaxis as for symptomatic AF (refer to section 6.3 for persistent AF, section 7.2 for permanent AF and section 8.2 for paroxysmal AF). **D(GPP)**

11.5 Risks of long-term anticoagulation

In order to provide adequate thromboprophylaxis with minimal risk of bleeding, current clinical practice aims for a target INR of between 2.0 and 3.0; INRs of more than 3.0 are associated with increases in bleeding and INRs of less than 2.0 are associated with increases in stroke risk.[176,182]

In one pooled analysis, the annual rate of major haemorrhage (defined as an intracranial haemorrhage, a haemorrhage requiring at least two units of blood, or an event requiring hospital admission) was 1% in control patients and 1.3% in warfarin-treated patients.[168] The annual risks of intracranial haemorrhage increased from 0.1% in control to 0.3% in warfarin groups, which represents an excess of two intracranial bleeds per annum per 1,000 patients treated. Even low-dose aspirin increases the risk of major haemorrhage by two-fold, especially in the settling of uncontrolled hypertension. Indeed, the correct treatment and monitoring of

hypertension and other associated comorbidities is regarded as extremely important in minimising the risk of bleeding in patients on prophylactic warfarin.

The most devastating complication associated with warfarin prophylaxis is the risk of intracranial haemorrhage, which is a particular problem in the elderly, in whom frailty, poor mobility, forgetfulness or poor compliance with medication, concomitant medications (resulting in drug interactions), and frequent falls may jeopardise the benefits from warfarin. These factors are often cited as reasons for non-prescription of warfarin in the elderly, where the absolute benefit is likely to be greatest in view of their high risk.[169]

There is also some evidence[268] that the combined use of warfarin with antiplatelet agents such as aspirin and clopidogrel significantly increases the risk of bleeding beyond that associated with the single use of any one of these agents. This raises a particular dilemma in those patients with both atrial fibrillation and coronary or peripheral artery disease, who are often co-prescribed warfarin and antiplatelet therapy. With the increasing use of drug-eluting stents, for which 6 to 12 months aspirin-clopidogrel use has recently been recommended, advice on how best to manage patients who have both AF and a drug-eluting stent who also require anticoagulation is currently lacking.[269]

This section aims to identify those risk factors for bleeding in patients with AF receiving oral anticoagulation.

11.5.1 Methodological introduction

'Long-term' anticoagulation was assumed to mean periods of anticoagulation administration of longer than 4 weeks. Studies that considered outcomes in populations with a mean period of anticoagulation of less than 4 weeks were excluded.

Studies were included in this report if they documented the incidence of complications associated with long-term oral anticoagulation, such as drug toxicity or adverse side effects, and measured and compared the risk of these complications between different groups of patients.

The reporting of risk will be made for both multivariate risk analyses, as well as univariate associations, wherever a multivariate calculation has not been reported.

11.5.2 Evidence statements

▷ Overall bleeding risk

One large study[270] (N=10,093) in an elderly population (mean age 77 years), reported a yearly incidence of 1.5% major bleeding events, of which 0.3% were intracranial haemorrhage.[28]

In another study[271] (N=677), in a population receiving both anticoagulation and antiplatelet therapy, the yearly incidence of major bleeding events was 1.1%, of which 0.6% were intracranial haemorrhage.[28] The study reported a yearly incidence of 11.8% minor bleeding events.[28]

▷ Bleeding risk factors

One study[272] found that patients older than 75 years were more likely to suffer bleeding complications than younger patients (2+). A similar result was found in another study.[273] (2+)

One small study[274] (N=101) did not find any significant difference in the incidence of bleeding complications between those aged 75 years or over and those aged 60 to 69 years. (2+)

Four studies[270,272,275,276] found no association between gender and bleeding complications, although female gender was found to be of borderline significance as an independent risk factor in two other studies.[270] (2+)

One study[271] failed to find diabetes to be a significant independent risk factor of bleeding complications (2+). A further three studies[272,275,276] failed to find any significant association between diabetes and bleeding. (2+)

One study[271] did not find hypertension to be a significant predictor of bleeding complications, although another larger study[168] found both systolic and diastolic blood pressure to be significantly higher in those patients with bleeding complications than in those without bleeding complications. (2+)

One study[270] found anaemia to be significantly associated with bleeding complications in an elderly cohort of patients. (2+)

Two studies[271,276] found a history of MI to be a significant independent predictor of bleeding complications (2+). A similar result was found for the presence of ischaemic heart disease.[276] (2+)

Two studies[271,272] failed to find a history of stroke or thromboembolism to be independent predictors of bleeding complications. (2+)

One study[276] did not find any significant association between cerebrovascular disease and incidence of bleeding complications although another larger study[277] found cerebrovascular disease to be a significant independent predictor of intracranial haemorrhage. (2++)

One study[270] found the concomitant use of antiplatelet drugs in anticoagulated patients to be a significant independent predictor of bleeding complications (2+). However, the same study did not find an increased number of additional medications – including non-steroidal anti-inflammatory drugs (NSAIDs) – to be a significant independent predictor of bleeding complications when risk was correlated with an increase of one additional drug. (2+)

One study[278] found a significant difference in bleeding complications between those patients prescribed at least three additional medications and those prescribed less than three. (2++)

One study[270] found a history of bleeding to be a significant independent predictor of future bleeding events. (2+)

11.5.3 From evidence to recommendations

The following risk factors were identified as being associated with bleeding in AF cohorts:

- over 75 years of age
- antiplatelet drug use
- uncontrolled hypertension
- history of bleeding or ICH
- anaemia
- polypharmacy.

It was considered unclear whether controlled hypertension or previous MI were independent predictors of stroke. For example, patients with previous MI were likely to be taking antiplatelet therapy, and may have other comorbidities, such as uncontrolled hypertension. Anaemia was a risk factor in the studies presented, probably because of an underlying bleeding source (eg peptic ulcer).

Poor anticoagulation control could also be considered as another risk factor for bleeding, particularly since the risk increased with INRs of greater than 3.0.[277] The use of concomitant antiplatelet therapy (aspirin or clopidogrel) was identified as a risk factor to bleeding; NSAIDs were thought to have a similar risk. Obvious bleeding factors, such as recent bleeding peptic ulcer or intracranial bleeding, are contraindications to anticoagulation, in view of the high risk associated with these conditions.

One criticism of the randomised trials is that they do not reflect real world practice, only randomising a minority of those screened, who tended to be at lower risk and monitored closely by intense trial protocols. One prospective UK cohort study, designed to determine if trial efficacy of warfarin for stroke prevention in AF translated into clinical effectiveness, reported that the rate of stroke (2% per year, 95% CI 0.7 to 4.4) compared with patients in the pooled studies (1.4% per year). Major bleeding rates (1.7% versus 1.6%) were also comparable.[176,279,280]

It was noted that many of the risk factors for bleeding (eg aged over 75 years, hypertension) were also risk factors for stroke (see section 11.6). Thus, it may be appropriate to undertake an assessment of bleeding risk as part of the clinical assessment of patients prior to starting antithrombotic therapy.

RECOMMENDATIONS

R55 Both the antithrombotic benefits and the potential bleeding risks of long-term anticoagulation should be explained to and discussed with the patient. **D(GPP)**

R56 The assessment of bleeding risk should be part of the clinical assessment of patients before starting anticoagulation therapy. Particular attention should be paid to patients who:

- are over 75 years of age **D**
- are taking antiplatelet drugs (such as aspirin or clopidogrel) or non-steroidal anti-inflammatory drugs **C**
- are on multiple other drug treatments (polypharmacy) **C**
- have uncontrolled hypertension **C**
- have a history of bleeding (for example, peptic ulcer or cerebral haemorrhage) **C**
- have a history of poorly controlled anticoagulation therapy. **D(GPP)**

11.6 Risk factors for stroke and thromboembolism

AF itself is an independent risk factor for stroke[14] and results in an independent increase in mortality *per se*.[11]

Stroke risk is also perceived to vary according to age and the presence of hypertension, diabetes mellitus, previous stroke or transient ischemic attack and poor cardiac function.

Transthoracic and transoesophageal echocardiography features have also been associated with a high risk of stroke (see section 4.3). Echocardiography therefore complements risk stratification on clinical grounds.

The objective of this section is to identify those risk factors for stroke or thromboembolism in patients with AF that should be incorporated into a comprehensive risk stratification algorithm.

11.6.1 Methodological introduction

All of the included studies were based in populations where the vast majority of people were receiving no anticoagulant drug during the course of the study period, and which identified independent risk factors of stroke or thromboembolism.

The use of aspirin or any other drug with presumed antithrombotic efficacy will not be reported here as a (negative) risk factor for stroke or thromboembolism. Echocardiographic risk factors are considered elsewhere (see section 4.3).

Although many studies considered the composite outcome of (ischaemic) stroke, TIA or thromboembolism, for the purposes of brevity this report will refer to the entire range of outcomes simply as 'stroke'.

11.6.2 Evidence statements

▷ Demographic risk factors

Of 10 studies that considered increasing age as a risk factor for stroke, either as a continuous variable or as incremental decades, six[168,192,281–284] found increasing age to be a significant risk factor, while the remaining studies[59,285–287] did not find increasing age to be significant. (2++)

Of three studies[60,288,289] that considered being elderly as a risk factor for stroke (by dichotomising age into younger and older age groups), one relatively small (N=272) study[60] did not find being aged over 70 years to be a significant risk factor (2+). In another study[288] (N=740) in a population with intermittent AF (at enrolment), being aged over 65 years was a significant risk factor for stroke (RR 3.3, 95% CI 1.92 to 5.81) (2+). In another study[289] (N=265) of a population without a previous stroke, being aged over 75 years was a significant risk factor for stroke (OR 1.72, 95% CI 1.04 to 2.84). (2+)

Based on the results of 11 studies[52,59,60,62,192,281–283,285,286,288] in various populations of AF patients, it is unclear whether gender is a significant independent risk factor. (2++)

One study[290] (N=854) found being female and over 75 years old to be a significant independent predictor of stroke (OR 3.7, 95% CI 2.2 to 6.2; $p<0.001$). (2++)

One study[168] (N=1593) did not find smoking to be a significant independent predictor of stroke (2+). However, the study did find a higher incidence of stroke in smokers than non-smokers ($p<0.05$). (2+)

▷ Clinical risk factors

Seven studies[62,168,192,281,283,284,287] found a history of stroke or TIA to be a significant independent predictor of secondary stroke (2++). Another study[285] based in a population with a prior stroke or TIA found a previous non-cerebrovascular thromboembolism to be a significant independent predictor of secondary stroke. (2++)

Based on the results of seven studies,[52,168,192,281,282,289,291] hypertension (controlled or uncontrolled) has been found to be a significant independent risk factor in both AF and atrial flutter (2++). However, another four studies[60,62,284,286] failed to find any significant relationship between hypertension and stroke. (2++)

Three studies[192,281,285] found systolic blood pressure greater than 160 mm Hg to be a significant independent predictor of stroke in general AF populations (2++). However, one study[192] failed to find it to be a significant independent risk factor specifically in patients with intermittent AF. (1+)

Based on the results of eight studies[52,60,62,168,282,284,287,290] that considered various measures of structural heart disease as risk factors for stroke, it is unclear whether congestive heart failure (CHF) is a risk factor for stroke[168,282,284,287] (2++), although the presence of structural heart disease generally has been found to be a significant independent predictor.[60] (2+)

One study[282] did not find the presence of ischaemic heart disease to be a significant independent predictor of stroke (2++). A similar result was found in the case of angina in another study.[168] (2+)

Two studies[168] found the presence of diabetes to be a significant independent predictor of stroke in a general AF population (2+). Another study[62] based in an elderly population did not find it to be an independent risk factor. (2+)

Two studies[282,286] based in AF populations without a previous stroke[286] or without any risk factors, including previous stroke and presence of CHF or left ventricular dysfunction,[282] did not find diabetes to be a significant independent predictor of stroke (2++). One study[291] based in a population with atrial flutter did not find diabetes to be a significant independent predictor of stroke. (2+)

Four studies considered a history of MI as a risk factor for stroke. Three studies[52,168,286] found MI to a significant independent risk factor (2+). The remaining study[62] based in an elderly population did not find MI to be a significant independent risk factor. (2+)

Two studies[60,284] did not find AF subtype (paroxysmal or non-paroxysmal) to be a significant independent predictor of stroke. (2++)

One study[285] based in a population with a previous stroke or TIA found an AF duration of greater than 1 year to be a significant independent predictor of secondary stroke. (2++)

One study[62] did not find obesity to be a significant independent predictor of stroke. (2+)

11.6.3 From evidence to recommendations

Many of the studies used highly selected populations that would affect the relative risk of the factors considered. The main data appraised came from cohort studies, epidemiological studies and clinical trials. Many of the clinical trials randomised only a small proportion of those initially screened, and excluded patients with valvular heart disease, thyroid disease or intercurrent illnesses such as chest infections.

Based on the evidence, the following were identified as independent risk factors for stroke in AF:

- previous stroke or TIA
- being elderly (aged over 75)
- structural heart disease
- hypertension
- previous MI.

The evidence for diabetes as an independent predictor of stroke in AF was not considered convincing, but overall was regarded as an important indicator for increased risk in the general AF population.

While MI was identified as an independent stroke risk factor, underlying left ventricular dysfunction may confound this result. Echocardiographically demonstrated left ventricular dysfunction is a known risk factor for stroke, but heart failure cannot always be diagnosed on clinical grounds alone. It was therefore agreed that heart failure should be on the list of risk factors even though the evidence was inconclusive.

Other risk factors such as peripheral artery disease were debated, but limited evidence was available. However, coronary and peripheral artery diseases were regarded as part of the clinical spectrum of atherothrombotic vascular disease that contributed to stroke risk. For example, complex aortic plaque on TOE was an independent stroke risk factor[292] (see section 4.3) and ischaemic stroke in AF could be associated with carotid artery disease.[293] For this reason vascular disease should be incorporated into a risk stratification model.

The evidence was unclear as to whether being female is a stroke risk factor. It was agreed that there was no known plausible biological reason for females with AF to have a higher stroke risk than men, and it was thus agreed that being female should not be included in any risk stratification algorithm.

Although none of the appraised studies considered AF patients with thyroid disease, it was agreed that this should not be considered as a risk factor for stroke.

All of the above factors, which are not mutually exclusive and may be cumulative, have been used in the development of various risk stratification algorithms (see Appendix B). These algorithms have been designed to assist the clinician in assessing individual patients for thromboprophylaxis. They can help in the identification of patients with AF who are at an increased risk of stroke and who would benefit most from anticoagulation therapy, while low-risk patients could be managed with antiplatelet therapy.

There is a need for an algorithm that stratifies stroke risk into three tiers to allow:

- high-risk patients to be identified for thromboprophylaxic anticoagulation therapy
- low-risk patients to be identified for antiplatelet use for thromboprophylaxis
- moderate-risk patients to be identified where further specialist referral may be necessary.

In addition to risk stratification it was accepted that patients preferences should be considered as some patients will still decline anticoagulation treatment for a variety of reasons. These include:

- the inconvenience of dosing adjustments and regular blood tests to monitor INR levels
- dietary restrictions
- the risk of minor and major bleeding, and
- under-appreciation or lack of knowledge regarding the risk of stroke, or poor adherence to the treatment regimen.

Many patients with AF possess limited knowledge of AF and its consequences and therapy. Only a minority reported feeling that their doctor had given them enough information about their warfarin therapy.

The following criteria were identified that should be addressed by any risk stratification algorithm for use in a UK population:

- incorporation of the risk factors identified above
- inclusion of a three-strata model (high, moderate and low risk)
- easy to use (no complex scoring system)
- patients with previous stroke or TIA automatically classified as high risk
- can be used for both primary and secondary prevention
- practical and applicable for use in both primary and secondary care.

A summary of the published risk stratification algorithms is shown in Appendix B. The benefits and drawbacks of each were discussed, with emphasis on a balance between evidence, clinical applicability and practicality, as well as refinement for a UK population. It was agreed that few had addressed the cumulative nature of risk factors where a combination (eg hypertension plus diabetes) would confer a greater risk than either alone.

It was noted that none of the published algorithms had been derived or validated in a UK population but one had subsequently been modified for this purpose.[294] Various other problems were highlighted regarding the applicability of the published algorithms:

- With the exception of one model,[283] non-warfarin trial participants had often been used as validation populations.
- One was based on a complex mathematical model.[283]
- Some only used a two-tier model (low and moderate–high risk) to stratify patients.[28,168,290,295]
- One was based on a point scoring system.[296]
- One did not necessarily identify a patient with a previous stroke or TIA as 'high risk'.[296]
- One model was only applicable for secondary prevention.[285]

It was agreed to suggest a revised algorithm based on the only model that had been optimised for use in a UK setting.[294] This was based on a modification of the AF investigators' algorithm,[168] but had been expanded into a three-tier model following consultation with primary and secondary care clinicians and was implemented (31/08/1997) and subsequently validated as a regional audit project in primary care by a large UK health authority.

RECOMMENDATIONS

R57 The stroke risk stratification algorithm (section 11.7) should be used in patients with AF to assess their risk of stroke and thromboembolism, and appropriate thromboprophylaxis given. **C**

R58 Risk stratification should be reconsidered whenever individual risk factors are reviewed. **D(GPP)**

11.7 Stroke risk stratification algorithm

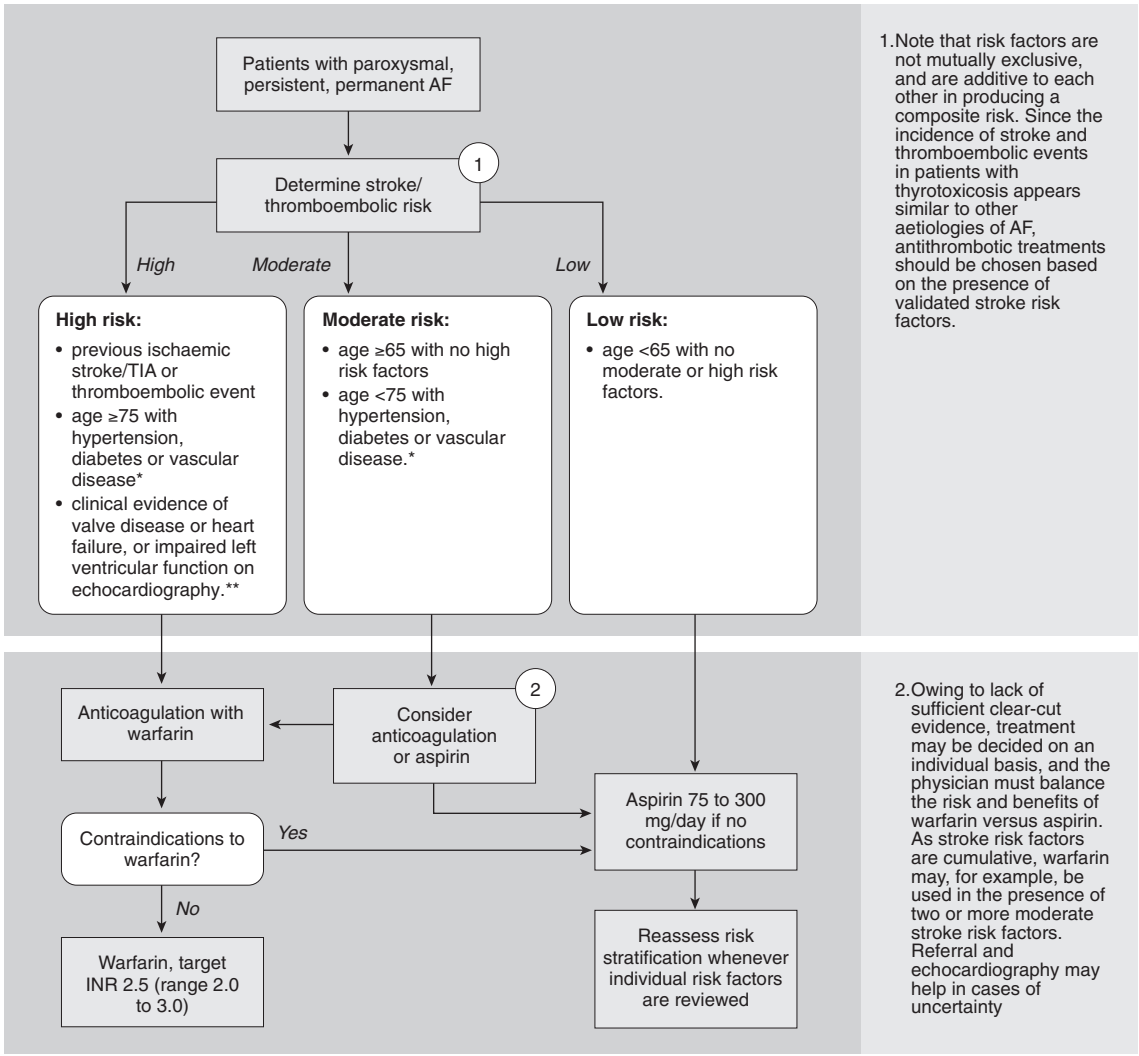

Figure 11.1 Stroke risk stratification algorithm. *Coronary artery disease or peripheral artery disease. **An echocardiogram is not needed for routine assessment, but refines clinical risk stratification in the case of moderate or severe LV dysfunction and valve disease.

11.8 The cost effectiveness of oral anticoagulation as thromboprophylaxis

The purpose of this section is to consider the health economic aspects of oral anticoagulation in patients with AF. In particular, since the risk of stroke is not homogenous throughout the AF population (see section 11.6), the administration of oral anticoagulation as thromboprophylaxis may be cost effective in high-risk patients, but not cost effective in lower risk patients. In those patients in whom oral anticoagulation is not cost effective, antiplatelet therapy may be more appropriate, or no treatment.

11.8.1 Methodological introduction

Eight published cost-effectiveness studies compared warfarin with no anticoagulation and/or warfarin with aspirin. Five of the cost-effectiveness studies were US-based,[297–301] two were conducted in the UK[302,303] and one in Sweden.[304]

Discounted survival or quality-adjusted survival was estimated using the prevalence over time of stroke, haemorrhagic events and mortality associated with AF. The ranges of outcomes incorporated in the models were very similar. All the studies drew from a relatively robust, up-to-date evidence of effectiveness of warfarin in preventing strokes. This is also presented in the review of effectiveness and consists of a meta-analysis of the effectiveness of warfarin in non-valvular AF patients.[305]

Most studies considered a healthcare system perspective (NHS for the two UK studies) and included discounted, direct costs of anticoagulation therapy (physicians or outpatient visits, drugs and prescription costs) and costs of hospitalisation for stroke and major haemorrhagic events.

11.8.2 Evidence statements

▷ Anticoagulation versus no anticoagulation

In general patients with AF, anticoagulation treatment is relatively cost effective compared with no anticoagulation. Three studies[297,300,302] reported on cost effectiveness of warfarin compared with no warfarin in a general AF population. The only UK study[302] reported an ICER ranging between £1,751 and £13,221 per life-year gained free from stroke. Studies from other countries reported cost-effectiveness ratios of US$1,907.[297] Another study[304] estimated that the cost per stroke prevented stratified according to risk of bleeding to be Swedish krona (SKR)171,000 per stroke prevented if the risk of bleeding is 0.3%, to SKR417,000 if the risk of bleeding is 2%. The other study[300] estimated a reduction in healthcare costs of US$1,514 per year.

Four studies[297–299,303] compared anticoagulation with no anticoagulation in patients with a low risk of stroke. In this subgroup of patients anticoagulation was found not to be cost effective, with higher costs and loss in quality of life compared with no anticoagulation.

In patients with medium to high risk for stroke, anticoagulation with warfarin was found to be cost effective, with estimated ICERs ranging between dominance[297,298] and ICERs of between US$1,434/QALY[299] and £6,000/QALY.[303] One study[303] also found that the ICER decreased as blood pressure increased.

In patients at high risk of stroke (more than two risk factors of stroke) all studies[297–299,303] found that anticoagulation was dominant, ie had lower costs and improved quality adjusted survival.

In elderly patients, the cost effectiveness of anticoagulation was found to depend on the level of risk of stroke. For high-risk patients, the ICERs ranged between dominance (lower costs and better outcomes) for individuals with high-risk factors.[297,299,302] For low-risk patients, anticoagulation was dominated by no anticoagulation.

▷ Anticoagulation versus antiplatelet therapy

Three studies[297,300,302] compared anticoagulation treatment with aspirin in general patients with AF. The ICERs ranged from US$2,000 in patients with low implantable cardiac defibrillator (ICH) risk (0.2%) to approximately US$7,000 in patients with high ICH risk (1.2%).[380] One study[297] had an ICER of US$4484/quality-adjusted life-years (QALY) while another study[300] found that warfarin treatment resulted in cost savings. Thus, in general patients with AF, warfarin was found to be cost effective compared with aspirin.

In low-risk patients, one study[298] estimated small improvements in QALYs which were realised at substantial costs compared with aspirin (US$370,000/QALY for 65 year olds and US$110,000/QALY for 75-year-olds).

In patients with AF who have a medium to high risk of stroke, one study[298] calculated an ICER of US$8,000/QALY for anticoagulation with warfarin. The cost-effectiveness advantage was found to decrease as the risk of bleeding increased.

In elderly patients with a moderate risk of stroke, one study[298] found that warfarin was cost effective compared with aspirin with an estimated ICER of US$500/QALY.

11.8.3 Evidence to recommendations

The health economic analysis suggested that the studies comparing warfarin with no anticoagulation and warfarin with aspirin were of good quality and summarised the evidence as follows:

- In patients with AF, anticoagulation treatment is cost effective compared with no anticoagulation.
- In patients at high risk of stroke, anticoagulation is cost effective, but not for those with a low risk of stroke.
- Aspirin is cost effective in low-risk patients compared with warfarin, but not in higher risk patients.

It was agreed that the health economics evidence was consistent with the stroke risk stratification algorithm (Figure 11.1).

12 Monitoring and referral

12.1 Anticoagulation self-monitoring

The increasing use of oral anticoagulation therapy as thromboprophylaxis in AF has increased the need for anticoagulation monitoring and encouraged a move towards 'point of care' or 'near patient' testing and patient self-monitoring. This may take several forms, whereby the patient has an anticoagulation-monitoring test performed at:

- the GP clinic using an INR testing machine based in the clinic itself, or
- the GP clinic but using an INR testing machine based in a central laboratory (normally at a hospital) where the blood sample is sent, or
- home using a personal INR testing machine allowing the patient to alter the dose of anticoagulation (self-monitoring).

Point of care for INR testing within primary care eliminates time lost in waiting for test results to be processed, by informing the patient of any changes to their INR and of any resulting change in dosing advice.[306]

Patient self-monitoring of oral anticoagulation gives a greater degree of autonomy. However, evidence is also required regarding the clinical utility and cost effectiveness of self-monitoring in order to recommend its routine use in clinical practice.

This section provides an opportunity to assess the evidence on whether self-monitoring is as effective as management using hospital laboratory testing and other conventional management strategies.

12.1.1 Methodological introduction

Studies were included if self-monitoring strategies were compared with traditional supervised-management strategies for the monitoring and dose-adjustment of long-term oral anti-coagulation. In the former case, self-monitoring could involve either the patient testing their own INR values and recording those values for appraisal by a supervising clinician responsible for dose-adjustment, or the patient performing both their own INR testing and dose-adjustment. In the latter case, testing was performed centrally or by clinicians using near-patient testing devices and clinicians made the dose-adjustment decisions.

The manufacturer or local distributor of the testing device funded all of the studies, either directly or indirectly.

Two studies had populations solely comprising AF patients.[307,308] The other studies included a proportion of AF patients within a general anticoagulated population[309–316] and others either included only patients with prosthetic heart valves[317,318] or did not report the number of patients with AF.[319–321] However, the results of the studies were consistent across all patient populations. A recently published meta-analysis[322] of 10 of the RCTs included in the guideline review was subsequently identified. The pooled results for relevant outcomes are included in the evidence statements below.

Two studies[323,324] were found that reported health economic outcomes of self-monitoring in comparison with supervised management. One study[323] was a cost-effectiveness analysis and the other[324] developed a comparative cost analysis where cost functions were developed and analysed to determine the break-even point in total cost between the two systems.

12.1.2 Evidence statements

Based on the results of 10 studies,[307,308,311,314–7,319–21] it is inconclusive whether self-monitoring is associated with improved control of INR compared with supervised management, when measured as the percentage of INR measurements within the target range. (**1++**)

No difference was found in the number of dose adjustments per INR measurement between self-monitoring (0.42) and supervised management (0.37)[312] (**2++**). However, the number of dose adjustments per patient was higher in the self-monitoring group (22.4 versus 3.4; $p<0.005$).[312] (**2++**)

Self-monitoring is associated with a lower rate of hospital admissions than supervised management in patients with prosthetic heart valves (15.3% versus 9.5%; $p<0.05$).[311] (**1+**)

When comparing self-management and supervised-management strategies, no significant association was found within individual studies in the rates of major thromboembolic or haemorrhagic complications.[307,310,312–315,318–20] A meta-analysis[322] of eight RCTs found self-management to be associated with significantly fewer major thromboembolic events (OR 0.41, 95% CI 0.25 to 0.70; p=0.001), but failed to detect a significant association for haemorrhagic complications (OR 0.66, 95% CI 0.37 to 1.16; p=0.15). (**1++**)

No significant difference in mortality rates between self-management and supervised-management strategies was detected within individual studies.[307,312,313,315,317–319] A meta-analysis[322] of five RCTs found self-management to be associated with significantly fewer deaths from all causes (OR 0.58, 95% CI 0.36 to 0.95; p=0.03). (**1++**)

One study[321] reported a higher incidence of major complications in those patients with conventional management than those with self-monitoring (7.3% versus 2.2%). (**1+**)

Self-monitoring was associated with a higher level of patient satisfaction and quality of life than supervised management when assessed by questionnaires.[313,318] (**1++**)

One cohort study reported patient preferences after study termination and 15 of the 17 patients from the self-monitoring group bought a near-patient testing device[307] (**2++**). The remaining two participants expressed a wish to purchase one but were financially unable to do so.

No significant association has been found between self-monitoring strategies that allow dose adjustment by patients and those where dose adjustment was determined by a clinician in terms of either the percentage of time spent within the target INR range (67% self-testing only versus 69% self-testing and self-dosing) or the percentage of measurements within the target INR range (64% self-testing only versus 66% self-testing and self-dosing).[314] (**1++**)

The cost-effectiveness results differed depending on whether or not costs incurred by patients and their carers are included with medical care costs.[323] Anticoagulation clinic testing versus usual care was cost saving when including medical costs only (US$405,560 versus US$419,514). Patient self-testing versus anticoagulation clinic testing had an incremental cost of US$24,818

per adverse event avoided or US$153,504 per QALY when including medical costs only. However, when including all costs, patient self-testing versus anticoagulation clinic testing was cost saving (US$622,727 versus US$645,671). Patient self-testing had higher medical care costs than usual care (US$526,014 versus US$419,514) but had a lower number of adverse events per 100 patients over 5 years (22.10 versus 30.65).

Results were sensitive to time spent below or above the therapeutic INR range and frequency of testing. Including medical costs only, there is approximately 80% certainty that anticoagulation clinic testing versus usual care is cost saving, and 48% certainty that patient self-testing versus anticoagulation clinic testing is cost saving.[323]

The use of near-patient testing costs less per year than conventional anticoagulation follow-up in self-care patients (€350.37N versus €378.36N, where N=number of patients). The yearly cost of near-patient testing is €133.77 plus €953.02N and equals the cost of conventional follow-up (€963.00N) when there are more than 14 patients on home-care follow-up. Sensitivity analysis indicates that small changes in the cost of near-patient management could affect the number of patients needed to make the near-patient model cost effective. The results were also sensitive to the travel costs.[324]

12.1.3 From evidence to recommendations

The evidence suggests that patient self-monitoring of oral anticoagulation is more effective in terms of patient satisfaction than supervised management.[313] However, the results of such trials should be interpreted carefully.

Many studies were conducted using a motivated patient population who were selected using strict inclusion criteria, which often included passing a cognitive test. In one study[307] the authors report that although at the end of the study period many patients wished to continue self-monitoring, this required sufficient personal financial resource to fund the purchase of the necessary equipment.

There was a difference in the cost effectiveness depending on whether patient and carer costs were included with medical costs. Further data based on the UK health setting would be required in order to determine the cost effectiveness of self-monitoring.

A recent non-commercially funded trial[325] which was published too late to be included in the above review, showed self-monitoring to be safe and effective in a UK population. This conclusion is consistent with the results from smaller trials above, most of which received commercial backing.

Increasing the adoption of self-monitoring might lead to additional pressure on GP services. It was considered that the use of self-monitoring needs to be balanced between patient preference and the ability of local services to provide support (eg patient education programmes).

It was noted that guidelines have been published in the area of patient self-monitoring of oral anticoagulation.[326] These recommend that patients undertaking anticoagulation self-monitoring should be trained by a competent healthcare professional and remain in contact with a named clinician. They also highlight the need for self-monitoring devices that have been adequately quality-assured.

RECOMMENDATION

R59 In patients with AF who require long-term anticoagulation, self-monitoring should be considered if preferred by the patient and the following criteria are met:

- the patient is both physically and cognitively able to perform the self-monitoring test, or in those cases where the patient is not physically or cognitively able to perform self-monitoring, a designated carer is able to do so
- an adequate supportive educational programme is in place to train patients and/or carers
- the patient's ability to self-manage is regularly reviewed
- the equipment for self-monitoring is regularly checked via a quality control programme. **C**

12.2 Follow-up post cardioversion

In current clinical practice review of patients after successful cardioversion is primarily to assess the maintenance of sinus rhythm. In addition the following factors are also considered:

- comorbid factors (eg heart failure, hypertension), by review
- adverse effects related to cardioversion (eg skin burns, thromboembolism)
- drug therapies (eg proarrhythmia from antiarrhythmic drugs, or bleeding from anticoagulation), and
- likelihood of arrhythmia recurrence, by assessment.

Those patients considered most likely to successfully cardiovert and maintain sinus rhythm are those who have recent onset AF (less than 12 months), those with no underlying structural heart disease, and those who have AF secondary to a precipitant (eg treated thyroid disease, fever) that has been successfully treated or corrected.

The consideration of symptoms alone as indicators of AF recurrence is not usually reliable, since many instances of recurrence occur asymptomatically.[64]

For patients with AF recurrence the decision needs to be made of whether another attempt at cardioversion should be undertaken, or a strategy of rate control should be adopted (see section 6.3), and whether the patient requires long-term antithrombotic therapy (see section 11.6).

12.2.1 Methodological introduction

Fifteen studies were included that compared different electrophysiological, radiological, clinical or demographic variables in those patients who maintained sinus rhythm post cardioversion and those who experienced AF recurrence. This information was assessed in order to recommend an optimal follow-up strategy.

The results of studies were reported only where a particular electrophysiological, radiological, clinical or demographic variable had been stratified into meaningful value ranges and the measurement of recurrence made over a specific follow-up period.

Studies that had follow-up periods of less than 1 week or that considered only specialist investigations, such as signal-averaged ECG recording, were excluded. Echocardiographic risk factors for AF recurrence are reported elsewhere (see section 4.3).

12.2.2 Evidence statements

Twelve studies reporting the proportion of patients with recurrent AF at different intervals following successful cardioversion are as shown in Table 12.1.

Table 12.1 Percentage of patients with AF recurrence following cardioversion

	Study	N	Patients	Prior CV	Period	Recurrence (%)
(2++)	Bollmann et al, 2003[327]	42	Recurrent	Yes	0.5	31
(2+)	Roijer et al, 2001[43]	62	Lone	No	1	32
(2+)	Dittrich et al, 1989[328]	65	Recurrent	No	1	31
(2+)	Duytschaever et al, 1998[46]	85	Recurrent	Yes	3.25	31
(2++)	Dmochowska-Perz et al, 2002[49]	112	Recurrent	Yes	6	55
(2++)	Aytemir et al, 1999[329]	74	Persistent	NR	6	42
(2+)	Okcun et al, 2002[330]	110	Recurrent	Yes	6	48
(2+)	Dittrich et al, 1989[328]	65	Recurrent	No	6	42
(2++)	Dogan et al, 2004[44]	64	Recurrent	No	6	44
(2++)	Guo et al, 2003[331]	60	Persistent	Yes	6	77
(2++)	Antonielli et al, 2002[42]	186	Recurrent	Yes	12	51
(2+)	Berry et al, 2001[332]	88	Recurrent	Yes	12	63
(2+)	Arnar and Danielsen, 1996[47]	44	Recurrent	Yes	12	43
(2+)	Paraskevaidis et al, 2005[50]	61	Lone	Yes	12	61
(2++)	Perez et al, 1997[333]	75	Recurrent	Yes	12	53

Prior CV = whether or not the patients enrolled in the study included those in whom a previous attempt at cardioversion had been performed.
Period = elapsed time since successful cardioversion (months).
Recurrence = percentage of patients with recurrent AF.

Up to 1 month following cardioversion, no significant differences have been found in any of the following pre-cardioversion factors in terms of the incidence of AF recurrence:

- presence of underlying heart disease[327] (2++) or cardiomegaly[208] (2+)
- gender[43] (2+)
- age greater than 70 years[43] (2+)
- AF duration of less than 2 weeks[43] (2+)
- use of antiarrhythmic drugs[43] (2+).

At approximately 3 months following cardioversion, no significant differences have been found in any of the following pre-cardioversion factors for the incidence of AF recurrence:[46] (2+)

- presence of underlying heart disease
- gender
- age greater than 70 years.

However, duration of AF of less than 12 months was found to be associated with an increased likelihood of maintaining sinus rhythm.[46] (2+)

At 6 months following cardioversion, the following pre-cardioversion factors have been found to be associated with an increased incidence of AF recurrence:

- a history of recurrent AF[49] (2++)
- chronic-obstructive pulmonary disease[330] (2+)
- heart failure.[49,330] (2++)

One study[44] found an AF duration of less than 5 days to be predictive of sinus rhythm maintenance at 6 months with sensitivity of 79% and specificity of 96% (2++). Another study[331] found AF duration to be significantly associated with incidence of AF recurrence when measured as a continuous variable, but not when dichotomised at 1 year. (2++)

Out of five studies[44,328–331] considering the association between gender and AF recurrence, only one[328] found a significantly higher proportion of men with AF recurrence at 6 months. (2++)

At 6 months following cardioversion, no significant differences have been found in any of the following pre-cardioversion factors in terms of the incidence of AF recurrence:

- age greater than 60 years[330] (2+)
- presence of any comorbid heart disease[44,331] (2+)
- presence of ischaemic heart disease[44,329–331] (2++), valvular heart disease[44] (2+) or cardiomegaly[334] (2+)
- presence of hypertension[44,329–331] (2++)
- presence of diabetes.[330] (2+)

At 12 months following cardioversion the following pre-cardioversion factors have been found to be associated with an increased incidence of AF recurrence:

- cardiomegaly[335] (2+)
- AF duration of more than 1 week.[42] (2+)

One study[335] reported a reduced risk of AF recurrence at 12 months among those patients in whom cardioversion was successful using only amiodarone prior to scheduled electrical cardioversion, compared with those in whom electrical cardioversion was required in addition to amiodarone (multivariate RR 0.075; 95% CI 0.01 to 0.54). (2++)

At 12 months following cardioversion the following pre-cardioversion factors have not been found to be associated with an increased incidence of AF recurrence:

- AF duration of more than 12 months[335] (2+) or 1 month[333] (2++)
- presence of ischaemic heart disease[42,333] or prior MI[42] (2++)
- presence of diabetes[42] (2++)
- presence of hypertension[42,333] (2++)
- gender.[50,333] (2++)

12.2.3 From evidence to recommendations

In terms of the incidence of recurrent AF, approximately one third of patients will relapse back to AF within the first month following successful cardioversion,[43,44,327,328] increasing to approximately half at 1 year.[42,47,50,332,333] There was not a large difference in the proportion of those reverting back to AF between 6 months and 1 year.

This suggests the need for routine follow-up for assessment at 1 month and 6 months following cardioversion. Those found still to be in sinus rhythm at 6 months could be discharged from secondary care and advised to attend primary care if symptoms re-occur.

A management strategy formulated prior to discharge from secondary care and shared with the patient's GP would be helpful in maintaining continuity of care.

The evidence was not considered strong enough to allow for the identification of specific patients in whom an alternative follow-up strategy would be beneficial.

It was agreed that the 1-month follow-up needs to be performed by a suitably trained healthcare professional.

In addition to assessing for relapse to AF, during each follow-up the clinician can take the opportunity to review:

- any comorbid factors (eg heart failure, hypertension)
- any adverse effects related to cardioversion (eg skin burns, thromboembolism)
- drug therapies (eg proarrhythmia from antiarrhythmic drugs, or bleeding from anticoagulation).

Furthermore, where a patient has relapsed to AF a decision needs to be made on whether an early attempt at a second cardioversion is appropriate or a rate-control strategy is more appropriate.

RECOMMENDATIONS

R60 Following successful cardioversion of AF routine follow-up to assess the maintenance of sinus rhythm should take place at 1 month and 6 months. **D**

R61 At the 1-month follow-up the frequency of subsequent reviews should be tailored to the individual patient taking into account comorbidities and concomitant drug therapies. **D**

R62 At each review the clinician should take the opportunity to re-assess the need for, and the risks and benefits of, continued anticoagulation. **D(GPP)**

R63 At 6 months, if patients remain in sinus rhythm and have no other need for hospital follow-up, they should be discharged from secondary care with an appropriate management plan agreed with their GP. **D**

R64 Patients should be advised to seek medical attention if symptoms recur. **D(GPP)**

R65 Any patient found at follow-up to have relapsed into AF should be fully re-evaluated for a rate-control or rhythm-control strategy (see section 6.3). **D(GPP)**

12.3 Referral

The purpose of this section is to identify which patients with AF might benefit from specialist investigations or interventions, but not to compare or contrast them with one another.

The most common reason for referral for specialist investigation or intervention is failed medical therapy due to antiarrhythmic drug intolerance or ineffectiveness. Secondly, those who may have an underlying electrophysiological problem, such as a pre-excitation syndrome due to an accessory pathway (eg Wolff–Parkinson–White syndrome) or those with focal AF, are commonly referred for pulmonary vein isolation. However, this procedure carries a small risk of pulmonary vein stenosis. Also, those with a family history of AF (familial AF)[336] may require specialist assessment. In addition, elderly patients may have sinus node disease that is associated with paroxysmal AF. Some[337] but not all[338] studies suggest a reduction in AF by atrial or physiological pacing. Pacemaker therapy in AF is also indicated for symptomatic low heart rates. Arrhythmia surgery, such as themaze operation, or less frequently, the corridor procedure, may be undertaken as a primary procedure – although uncommonly in the UK – or during associated cardiac surgery (eg mitral valve surgery).[339–341]

In drug-resistant, poorly tolerated AF, atrioventricular junction (AVJ) catheter ablation is an option.[342] A recent meta-analysis[343] of before-after studies in AVJ ablation and pacing showed a beneficial effect in terms of symptom severity, exercise tolerance, cardiac physiology and function, as well as hospital admissions. However, 'ablate and pace' carries a small risk of sudden death.[344,345]

Using technology similar to implantable cardioverter-defibrillators for ventricular arrhythmias, an atrial defibrillator (atrioverter) re-establishes sinus rhythm and reduces recurrences of persistent AF.[346] There is conflicting evidence on the tolerability of atrial defibrillators and of the risk of ventricular proarrhythmia.

12.3.1 Methodological introduction

Studies were included if either:

- a comparison was made between a medical treatment strategy that involved the use of either pharmacological intervention and/or electrical cardioversion (internal or external) and other device or procedure-based treatments, or
- the study compared the safety or efficacy of other device or procedure-based treatments or investigations between different patient subgroups (defined by either demographic, clinical or physiological characteristics).

Studies that compared two device- or procedure-based treatments (for example, two variants of the maze procedure) were not considered.

The following categories of device or procedure-based treatments were included:

- pulmonary vein isolation
- pacemaker therapy
- arrhythmia surgery
- AVJ catheter ablation
- atrial defibrillators.

The majority of studies not involving concomitant cardiac surgery included only medically-refractory patients. Such patients are defined in this report by: an explicit report of refractoriness in the study inclusion criteria; reported resistance to a mean of at least two antiarrhythmic drugs; or the report of patients experiencing intolerable symptoms associated with AF, either in terms of severity or (in the case of paroxysmal AF) frequency of episodes.

12.3.2 Evidence statements

▷ Pulmonary vein isolation

One study[347] comparing pulmonary vein isolation (PVI) with amiodarone therapy in a population of amiodarone-naïve patients with medically-refractory non-valvular recurrent AF found PVI to be associated with a higher prevalence of sinus rhythm at 12 months (p=0.03) and improved quality of life (p=0.048). (**1+**)

One study[348] in a population of relatively young (mean age 54 years) patients with recurrent AF (mostly PAF) with no previous use of antiarrhythmic drugs found that PVI was associated with higher rates of sinus rhythm maintenance at 12 months than pharmacological therapy with antiarrhythmic drugs (87% versus 37%; p<0.001) (**1+**). Those patients undergoing PVI also had fewer hospital admissions than those treated with drugs (9% versus 54%; p<0.001) (**1+**). In terms of quality of life, PVI was associated with a greater improvement in the following Short-Form 36 health survey subscales than drug therapy: (**1+**)

- general health
- physical functioning
- role physical
- bodily pain.

The study reported comparable efficacy between PVI and drug therapy in all other aspects of quality of life.

Two studies[349,350] found increasing age to be significantly associated with an increased incidence of AF recurrence following PVI (**2+**). However, another study[351] in a population with paroxysmal lone AF did not find age to be a significant independent predictor. (**2+**)

The results of one study[352] in patients with medically-refractory AF and a history of isthmus-mediated atrial flutter found men less likely to maintain sinus rhythm following PVI (**2+**). Another study[351] found no effect of gender and a successful outcome at 3 months. (**2+**)

Three studies[349,352,353] found that those with medically-refractory paroxysmal AF are more likely to maintain sinus rhythm following PVI than those with medically-refractory non-paroxysmal AF (**2+**). Those with medically-refractory paroxysmal AF were also found to be more likely to benefit from PVI than those with persistent AF in terms of overall treatment success (restoration and maintenance of sinus rhythm or significant improvement in symptoms at 5 months).[353] (**2+**)

One study[350] found that those with medically-refractory lone paroxysmal AF are more likely to benefit from PVI than those with comorbid paroxysmal AF in terms of prevalence of sinus rhythm at 1 month (**2+**). The results for other populations with medically-refractory lone AF is unclear.[349,352] (**2+**)

Those without a history of paroxysmal AF[353] or hypertension,[354] a left atrial diameter less than 40 mm[350] and normal left ventricular function[355] are more likely to benefit from PVI in terms of the maintenance of sinus rhythm. (2+)

▷ Pacemaker therapy

One crossover study[356] found that bi-atrial pacing was associated with a significant reduction in the amount of time spent in AF over 3 months compared with no pacing (1+). A similar result was found for right-atrial pacing alone (1+). However, no significant difference was found in terms of the frequency of AF episodes. (1+)

One small study[357] found no difference in the prevalence of structural heart disease among those maintaining sinus rhythm and those with AF recurrence following successful internal cardioversion and pacing of patients with permanent AF (63% versus 100%). (2+)

▷ Arrhythmia surgery

One study[358] of patients with AF undergoing a combined cardiac procedure with a modified maze procedure using cryoablation had a higher prevalence of sinus rhythm in the acute postoperative period compared with those undergoing cardiac procedures without any concomitant antiarrhythmic surgery (84% versus 6%; $p<0.0001$) (2+). The modified maze procedure was also associated with longer intubation and recovery times, as well as higher pulmonary artery and central venous blood pressure (2+). In the long term, the antiarrhythmia surgery was also associated with an improved NYHA grade. (2+)

Six studies[359–364] found that combining mitral valve procedures with antiarrhythmia surgery (the maze procedure or variants thereof), was more effective in restoring and maintaining sinus rhythm than mitral valve surgery alone for at least 3 years postoperatively. (1+)

One study[362] found the combination of mitral valve surgery and the maze procedure to be ineffective in improving any echocardiographically detected measure of cardiac physiology (including LVEF and left atrial diameter) compared with mitral valve surgery alone over 3 months and 12 months postoperatively (1+). Another study[363] found a similar result in NYHA grade over the same period. (1+)

One study[358] in a population with a mean duration of AF of approximately 8 years found the combination of mitral valve surgery and a modified maze procedure using cryoablation to be effective in reducing the cardiothoracic and the left atrial diameter compared with mitral valve surgery alone. (2+)

One study[362] found no differences in exercise tolerance between those patients undergoing combined mitral valve and maze surgery and those undergoing mitral valve surgery alone (1+). Another study[363] found a similar result, with the exception of maximum workload which was higher in those undergoing the maze procedure. (1+)

No significant beneficial effect of combining the maze procedure with cardiac surgery has been reported in terms of either quality of life[362] or mortality[364] at 12 months (1+). However, there is limited evidence[360] to suggest a reduction in adverse vascular events (stroke or anticoagulated-related bleeding events). (2+)

One study[365] found that combining mitral valve procedures with the corridor procedure resulted in more effective ventricular rate control than mitral valve surgery alone. (2+)

LAA filling velocity less than 20 cm/sec,[366] a duration of AF more than 10 years,[366] an enlarged left atrium[366–368] and an F wave less than 1 mm[368] are all associated with a reduced likelihood of sinus rhythm restoration and maintenance during the early postoperative period following combined cardiac surgery with PVI. (2+)

An enlarged left atrium has also been found to be associated with a longer time taken to revert to sinus rhythm following combined mitral valve surgery with the maze procedure,[369] as well as a longer time taken for the restoration of atrial contractile function in those in whom sinus rhythm was restored.[370] (2+)

It is unclear whether an enlarged left atrium is associated with a reduced likelihood of AF recurrence in the longer term after combined cardiac and antiarrhythmic surgery[369–371] (2+). However, one study[372] found a left atrial diameter of less than 57.8 mm and a left-atrial area of less than 56.25 cm^2 to have some degree of power in predicting the maintenance of sinus rhythm at 38 months following combined mitral valve surgery with the maze procedure. (2+)

One study[367] reported that the sensitivity and specificity of the regression equation 1.39-(0.387GLA)-(0.01AFD)-(0.007Age), where values over 0.843 predict postoperative sinus rhythm, was 73.2% and 88.9%, respectively (2+) (Note that GLA = 1 for the presence of a giant left atrium, 0 otherwise, and AFD is the duration of AF). However, the expression has not been validated prospectively in a separate cohort of patients.

▷ Atrioventricular junction ablation

Compared with continued pharmacological therapy, AVJ ablation is associated with a significant reduction in the number of hospital admissions[373,374] (1+), as well as the incidence of CHF.[374] (2+)

Three studies[342,373,374] found that AVJ ablation was more effective in reducing the overall severity of symptoms of AF compared with continued pharmacological treatment. (1+)

Four studies[342,373–375] are consistent in demonstrating a reduction in all symptoms commonly associated with AF, with the exception of syncope and resting dyspnoea, following AVJ ablation compared with continued pharmacological treatment (1+). However, two studies[342,375] failed to find any significant improvement in terms of overall quality of life. (1+)

The results of one study[374] in a population with lone AF found a difference in mean NYHA grade between AVJ ablation and pharmacological treatment in favour of AVJ ablation (2+). A consistent result was also found in a population with paroxysmal AF,[373] although the difference was not significant (1+). Another study[342] found no significant difference in terms of left-ventricular fractional shortening (LVFS). (1+)

One study[373] found that 24% of patients who underwent AVJ ablation developed permanent AF within 6 months, compared with no patients who continued pharmacological treatment (p=0.04) (1+). Another study[376] reported that those older than 75 years or those with comorbid cardiovascular disease are at an increased risk of developing permanent AF following AVJ ablation. (2+)

▷ Atrial defibrillator

The use of an atrial defibrillator with the defibrillator function activated is associated with a reduced burden of AF and a reduction in the number of hospital admissions compared with when the defibrillator function is de-activated[377] (2+). No significant association has been reported between the degree of patient acceptance of the implantation and use of an atrial defibrillator and patient age, gender, or the number of cardioversions performed pre-implantation.[378,28]

12.3.3 From evidence to recommendations

▷ Pulmonary vein isolation

From the evidence, it was noted that patients with the following characteristics may benefit from referral for PVI:

- patients who were resistant to pharmacological treatment
- younger rather than older patients or
- those with lone AF.

It was recognised that many of these patients may have focal AF secondary to a pulmonary vein foci and for those patients PVI may be a useful procedure.

▷ Pacemaker therapy

Other than recognised indications for pacemaker implantations such as sinus node disease, symptomatic bradycardia and chronotropic incompetence, no evidence was found to specifically identify other patients with AF who should be referred for pacemaker implantation.

▷ Arrhythmia surgery

Other than patients undergoing concomitant cardiac surgery (eg mitral valve surgery), there was no evidence to specifically identify patients for referral for arrhythmia surgery other than those who had failed other treatment options.

▷ AVJ catheter ablation

It was concluded that this technique was effective for patients with medically refractive paroxysmal AF, especially in the absence of any cardiac comorbidity.

▷ Atrial defibrillators

This technique was considered to be useful in patients with recurrent persistent AF but it should not be used in those with paroxysmal AF.

RECOMMENDATIONS

R66 Referral for further specialist intervention (for example, pulmonary vein isolation, pacemaker therapy, arrhythmia surgery, AVJ catheter ablation or use of atrial defibrillators) should be considered in the following patients:

- those in whom pharmacological therapy has failed **B**
- those with lone AF **B**
- those with ECG evidence of an underlying electrophysiological disorder (eg Wolff–Parkinson–White syndrome). **C**

R67 The reasons for referral for specialist intervention should be explained and discussed with the patient. **D(GPP)**

Appendix A: Health economics modelling

The GDG selected a number of questions for which they felt more detailed health economic input would be useful. The following three areas were given priority:

- Economic analysis of the routine use of echocardiography versus selective use in clinical practice (routine ECHO model).
- Cost-effectiveness analysis of using TOE-guided CV in patients presenting with AF lasting for more than 48 hours for the presence of thrombi before cardioversion compared with conventional 3 to 4 weeks of anticoagulation (TOE model).
- The cost effectiveness of warfarin administration in AF patients, particularly the elderly (warfarin model).

No additional modelling was performed in the guideline on these topics for the reasons outlined below.

Routine ECHO model

When the model was presented to the GDG for discussion, the group were uncomfortable with the number of assumptions required for the model and the data sources used to obtain these. The GDG felt that the need to obtain health economics evidence for routine ECHO had been superseded, since routine ECHO is not going to be recommended. The recommendation for ECHO would be based on risk stratification and clinical criteria. The group voted to move on to the next topic for modelling.

TOE model

The health economist advised that a complex model was required to overcome limitations of the ACUTE trial. The technical team felt it would be difficult to populate this model with reliable data and were wary that the GDG would not be comfortable with a large number of assumptions. The project executive, aware of time constraints, advised that a rapid costing of the ACUTE trial was the only feasible option. Guidance was sought from health economist Jo Lord who advised that the costing of the ACUTE trial would be a misleading enterprise. The main concern was that the trial fails to establish the clinical superiority of the TOE strategy compared with the conventional anticoagulation strategy. A model designed on those data would have to incorporate an increase in mortality with TOE-guided CV. For this reason it was difficult to justify the rationale for conducting this cost-effectiveness analysis. Because of this, the TOE-guided CV model was not pursued.

Warfarin model

A review of the published cost-effectiveness literature was undertaken for this area prior to undertaking the modelling exercise. A large number of studies were identified (N=8) and thus it was agreed that there was sufficient literature to answer the question and no further analysis was required.

Appendix B: Stroke risk stratification models

Stroke risk stratification models

Ref no.	Criteria (year)	Type	IV	EV	Low-risk criteria	Medium-risk criteria	High-risk criteria
379	ACCP 1 (1998)	1°/2°	No	Yes	No medium or high-risk factors	Diabetes coronary artery disease Thyrotoxicosis Age 65 to 75 years	Age >75 years History of hypertension Moderate–severe LV systolic dysfunction (by echocardiography)
202	ACCP 2 (2004)	1°/2°	No	No	No medium or high-risk factors	Age 65 to 75 years	Prior stroke/TIA or systemic embolism Age >75 years Moderate–severe LV systolic dysfunction (by echocardiography) Diabetes Hypertension
168	AFI 1 (1994)	1°/2°	Yes	Yes	No risk factors	Previous stroke or TIA History of hypertension History of diabetes Age >65 years	
294	AFI 2 (1999)+	1°/2°	No	No	Age <65 with no history of embolism, hypertension, diabetes, or other clinical risk factors	Age <65 with clinical risk factors: diabetes, hypertension, peripheral arterial disease, ischaemic heart disease. Age >65 not in high-risk group	Previous stroke or TIA Age ≥75 years AND hypertension and/or diabetes Clinical evidence of valve disease, heart failure, thyroid disease, and/or impaired left ventricular function on echocardiography
28	AFI 3 (2003)	1°/2°	Yes	Yes	No risk factors	Previous stroke or TIA Treated hypertension OR systolic blood pressure ≥160 mm Hg Previous MI OR angina Diabetes

281	SPAF 5 (1999)	1°	Yes	No	No risk factors	Hypertension AND age ≤75 years Diabetes	Systolic blood pressure >160 mm Hg Hypertension AND age >75 years Female AND age >75 years

+AFI2 [294] was based on the initial AFI1 [168] risk stratification, but refined for a Birmingham primary care population by the AF Clinical Effectiveness Topic Group on behalf of the Birmingham Effectiveness Group, commissioned by Birmingham Health Authority. This was then implemented (31/8/97) as *Clinical Management in General Practice Guidelines* of the Birmingham Medical Audit Advisory Group and as a pan-Birmingham audit project in primary care by the Birmingham Health Authority.
*The CHADS2 system is based on the AFI1 and SPAF1 risk criteria, and assigns one point to CHF, hypertension, age >75, diabetes mellitus and two points to a previous stroke or TIA;
**Framingham 2003 assigned points to incremental increases in age (0 to 10 points) and blood pressure (0 to 3 points), and 6 points for being female, 5 points for diabetes and 6 points for a previous stroke or TIA. Risk stratification was made for CHADS2 and Framingham 2003 based on expected incidence of <2%, 2 to 6%, and >6% for low, medium and high-risk patients, respectively (using original cohort data).

Appendix C: Clinical questions and search strategies

The table below lists all of the systematic reviews of the relevant literature that were performed as part of the development process of this guideline. In each case the section number of this guideline is given where the results of the systematic review are presented, along with the clinical question asked, and the corresponding search strategy used.

Clinical questions and search strategies

Section number	Question wording	Study type filters used	Databases and years
4.1	In patients with diagnosed AF (including those presenting with stroke), what are the frequencies of the presenting symptoms?	All study types including hospital- and population-based	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005
4.2	In patients with suspected AF based on an irregular pulse, how accurate is an ECG in diagnosing AF?	Diagnosis	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005
4.3	In which patients should echocardiography be performed to identify underlying structural/functional heart disease?	Diagnosis	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005
4.4	In patients with suspected intermittent AF, how effective is ambulatory ECG rather than event ECG in diagnosing AF?	Diagnosis	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005
5.1	Does electrical conversion versus pharmacological conversion affect rates of thromboembolism, quality of life, exercise capacity, failure rates?	All study types	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005
5.2	In patients with persistent AF, is amiodarone better than a) flecainide or b) propafenone for use in cardioversion?	Systematic reviews, RCTs and comparative studies	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005
5.2	In patients with AF is amiodarone better than sotalol for use in cardioversion?	Systematic reviews, RCTs and comparative studies	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005
5.3	What is the safety and efficacy of the adjunctive administration of antiarrhythmic drugs for use in electrical cardioversion in comparison to electrical cardioversion without adjunctive antiarrhythmic drugs?	Systematic reviews, RCTs and comparative studies	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005

11.6	In patients with AF, what are the risk factors associated with stroke/TIA and thromboembolism?	Risk, systematic reviews, RCTs, comparative studies and observational studies	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005
12.1	In patients receiving anticoagulation therapy, is self-management using near-patient testing devices in primary care as effective as management using hospital lab testing?	Systematic reviews, RCTs, comparative studies, case control and observational studies	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005 BNI 1985–2005
12.2	When should a cardioverted patient be followed up after cardioversion?	Systematic reviews, RCTs, comparative studies and observational studies	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005
12.3	Which patients with AF benefit from referral to specialist services for non-pharmacological treatment or electrophysiological studies?	Systematic reviews, RCTs, comparative studies and observational studies	Medline 1966–2005 Embase 1980–2005 Cochrane 1800–2005 Cinahl 1982–2005

Note: The final cut-off date for all searches was 6th June 2005.

Appendix D: Drug classification and licensing

Wherever appropriate, throughout this guideline recommendations have been formulated in terms of drug classes rather than individual drugs. The Vaughan-Williams system for classifying antiarrhythmic drugs such as flecainide (Class Ic) and amiodarone (Class III) has been used where appropriate.

In the case of rate-limiting calcium antagonists, certain drugs within this class may not be indicated for the treatment of AF. In particular, the rate-limiting calcium antagonist diltiazem hydrochloride is not indicated for AF, but nonetheless has a substantial evidence-base supporting its use.

Beta-blockers represent a wide range of agents, with different degrees of cardioselectivity. Certain beta-blockers may not be licensed specifically for AF. Sotalol is a beta-blocker that has additional Class III antiarrhythmic activity at high doses (240 to 480 mg/day). In UK practice, sotalol is often used at low doses (80 to 160 mg/day), which essentially acts in a similar manner to a standard beta-blocker (Class II) in terms of antiarrhythmic activity. In some patient groups (for example, those with a low body mass index or renal impairment), some Class III activity may even manifest at these low doses. In general, when used as a Class III antiarrhythmic agent, sotalol is often started at a dose of 80 mg twice daily for the first week and subsequently titrated to 160 mg twice daily or even higher doses after checking for adverse effects and QT prolongation on ECG.

Appendix E: Glossary of terms

Absolute risk reduction (**ARR**) The difference between the percentage incidence of adverse outcomes in the test group compared with the control group in a controlled trial, eg if the stroke rate in warfarin-treated patients is 2% compared with 5% in non-warfarin treated patients, warfarin is associated with an absolute risk reduction of 3%.

Accessory pathway An abnormal conduction circuit within the heart resulting in abnormal heart rhythms.

Adjusted dose The situation where the dosage of a drug is adjusted to attain a particular physiological value, eg the dosage of warfarin may be adjusted to attain a particular INR value.

Adverse event An event that occurs, normally as part of a pathological process or as an unintended consequence of a therapeutic intervention, which is considered to be of detrimental value to the patient in terms of their health or quality of life, eg the development of pulmonary fibrosis consequent to the long-term administration of amiodarone.

AF burden A measure of the degree to which the presence of AF has a detrimental effect on the patient's quality of life. It is normally measured either as the proportion of time spent in AF, or the number of AF episodes per unit time.

AF pathophysiology The pathological progression of AF in terms of the degeneration of the arrhythmia to a more sustained and/or symptomatic form, or the development of associated co-morbidities.

AF recurrence The recurrence of an episode of AF following one or more prior episodes of the arrhythmia in either its paroxysmal or persistent form.

AF subtype A subtype of AF based on its temporal pattern. AF subtypes are recent onset, paroxysmal, persistent and permanent.

Algorithm (**in guidelines**) A flowchart of the clinical decision pathway described in the guideline, where decision points and actions are represented by different shaped boxes and linked by arrows.

Ambulatory-ECG An ECG monitoring tool in which a continuous ECG recording is made while the patient remains able to walk around freely and pursue most normal daily activities.

Antiarrhythmic A drug or interventional procedure that has a therapeutic effect against cardiac arrhythmias.

Anticoagulation A form of thromboprophylaxis involving the use of anticoagulant drugs such as warfarin that inhibit the coagulation/clotting of blood.

Antiplatelet therapy A form of thromboprophylaxis involving the use of antiplatelet drugs (such as aspirin) that inhibit the formation of blood clots.

Antithrombotic therapy See 'thromboprophylaxis'.

Aortic plaque The deposits of atherosclerotic plaque within the aorta. The extent of aortic plaque is classified as 'simple', 'moderate' or 'complex'.

Aortic stenosis An abnormal narrowing of the aortic valve.

Arrhythmia An irregularity in the coordinated rhythm of the heart.

Arrhythmia surgery Antiarrhythmic surgical interventions to treat the abnormal heart rhythm, eg the 'maze' procedure, corridor operation. See also 'antiarrhythmic'.

Atrial arrhythmias Cardiac arrhythmias that originate in the atria. AF is an atrial arrhythmia. See also 'arrhythmia'.

Atrial contractile function A measurement of the contractile function of the atria. This is normally measured using echocardiography.

Atrial defibrillator See 'cardioverter defibrillator'.

Atrial fibrillation (AF) An atrial arrhythmia characterised by an absence of regular P waves on an electrocardiogram, and normally resulting in a fast ventricular response. See also 'atrial arrhythmia'.

Atrial filling fraction A measurement of the contractile function of the atria. This is normally measured using echocardiography.

Atrioventricular node ablation Use of energy (usually radiofrequency) to destroy tissue of the atrioventricular node to alter conduction of electrical signals through this part of the heart.

Atrioventricular-blocking drug A drug that inhibits the ability of the atrioventricular node to conduct electrical signals to the ventricles.

Audit See 'clinical audit'.

Binary A clinical variable or outcome is binary when it can only take on two possible values. In some cases variables that can take on more than two possible values, such as age, are dichotomised at a particular value to create a binary variables, such as 'under 65' and '65 or over'.

Bradycardia A slow heart beat. The occurrence of bradycardia is often recorded as an adverse event to some antiarrhythmic or chronotropic drugs. Such occurrences are referred to as bradycardic events.

Cardioembolic stroke An embolic stroke whose aetiology is presumed to be the embolisation of an intracardiac thrombus.

Cardiomegaly An abnormal enlargement of the heart. It is normally measured in terms of the cardiothoracic ratio from a chest X-ray or by measurement using echocardiography.

Cardiomemo An event recorder that records cardiac rhythm when activated by the patient.

Cardiothoracic ratio (CTR) See 'cardiomegaly'.

Cardioversion In the context of AF, cardioversion is the process of restoring normal sinus rhythm. There are two commonly used forms of cardioversion: electrical cardioversion and pharmacological cardioversion. The former involves the administration of a transthoracic electrical shock; the latter involves the administration of antiarrhythmic drugs.

Cardioverter defibrillator A defibrillator device that is implanted into the patient's chest to deliver an electrical shock to cardiovert episodes of AF. The device may be automated – automatic implanted cardioverter defibrillator – or patient-triggered. See also 'defibrillator'.

Case series Report of a number of cases of a given disease, usually covering the course of the disease and the response to treatment. There is no comparison (control) group of patients.

Case-control study Comparative observational study in which the investigator selects individuals who have experienced an event (for example, developed a disease) and others who have not (controls), and then collects data to determine previous exposure to a possible cause.

Cerebral infarction Damage to the brain following a reduction of blood supply to that area, resulting in a stroke.

Cerebrovascular disease Disease of the blood vessels within the brain. Cerebrovascular disease can be caused by blocked or otherwise damaged blood vessels and is the cause of strokes. See also 'stroke'.

Chronotropic In the context of pharmacology, the ability of a therapeutic intervention to control heart rate.

Chronotropic incompetence The inability of the body to appropriately alter heart rate during periods of physical exertion. See also 'chronotropic'.

Clinical audit A quality improvement process that seeks to improve patient care and outcomes through systematic review of care against explicit criteria and the implementation of change.

Clinically significant The result of a study is clinically significant if it is felt that the demonstrated difference in outcomes between the different arms of the study have the potential to inform and change clinical practice. A result may be statistically significant but not clinically significant, and vice versa.

Cohort study A retrospective or prospective follow-up study. Groups of individuals to be followed up are defined on the basis of presence or absence of exposure to a suspected risk factor or intervention. A cohort study can be comparative, in which case two or more groups are selected on the basis of differences in their exposure to the agent of interest.

Comparable In a statistical sense, a therapeutic intervention is said to be comparable to another if there is no statistically significant difference between them.

Compliance The extent to which a patient complies with a recommended treatment regimen.

Confidence interval (CI) A range of values which contains the true value for the population with a stated 'confidence' (conventionally 95%). The interval is calculated from sample data, and generally straddles the sample estimate. The 95% confidence value means that if the study, and the method used to calculate the interval, is repeated many times, then 95% of the calculated intervals will actually contain the true value for the whole population.

Confound The results of a study are confounded when there are thought to be other variables that were not controlled for in the study design, and where the effects of those variables on the results are unquantifiable and variable.

Congestive heart failure (CHF) Heart failure characterised by the inability of the heart to adequately support the body's physiological requirements.

Conventional anticoagulation The use of oral anticoagulation as a means of thromboprophylaxis, aiming for a target INR (usually 2.5, range 2–3) with monitoring and dose adjustment in an anticoagulation clinic. In the context of cardioversion, this is contrasted with the use of transoesophageal echocardiography to screen for the presence of thrombi and the use of parenteral anticoagulation prior to cardioversion, thus excluding the pre-cardioversion initiation of anticoagulation.

Coronary artery disease A disease which affects the arteries of the heart, normally through atherosclerosis of the coronary arteries, reducing the supply of blood to the heart and causing ischaemia and angina. See also 'ischaemic heart disease'.

Cost function A function that describes the relationship between the input prices such as labour costs, drugs, hospital stay and the quantity of outputs (health outcomes). It describes the opportunity cost, that is, what needs to be sacrificed in monetary terms in order to gain certain outcomes.

Cost effectiveness A measure of effectiveness that is relative to cost. For example, the cost effectiveness of antithrombotic therapy to prevent strokes may be measured in terms of the cost per stroke prevented. See also cost-effectiveness analysis and cost-effectiveness model.

Cost-effectiveness analysis An economic study design in which consequences of different interventions are measured using a single outcome, usually in natural units (for example, life-years gained, deaths avoided, heart attacks avoided, cases detected). Alternative interventions are then compared in terms of cost per unit of effectiveness.

Cost-effectiveness model An explicit mathematical framework, which is used to represent clinical decision problems and incorporate evidence from a variety of sources in order to estimate the costs and health outcomes.

Cost–utility analysis A form of cost-effectiveness analysis in which the units of effectiveness are quality-adjusted life-years (QALYS).

Coumarin derivative An anticoagulant drug that is derived from coumarin. Examples of coumarin derivatives include the anticoagulant warfarin.

Crossover study A study design in which the participants are first administered the control intervention, followed by the test intervention, or vice versa. In between these two study phases there is normally a wash-out period in the case of drug trials, so that the levels of the control or test drug falls to negligible amounts before the next phase of the study begins.

Cryoablation Use of cold energy ('freezing') to destroy tissue within the heart in order to alter conduction of electrical signals through this part of the heart.

CT scan Computed tomography scan, an imaging technique using X-rays.

Day case In the context of cardioversion, a day case refers to the discharge of patients following elective cardioversion on the same day on which they were admitted.

Decision analytic model/techniques A way of reaching decisions, based on evidence from research. This evidence is translated into probabilities and then into diagrams or decision trees that direct the clinician through a succession of possible scenarios, actions and outcomes.

Decision model A systematic framework of representing a clinical problem under conditions of uncertainty. It is used to determine the costs and health outcomes of a hypothetical patient cohort with disease of interest when they are treated with different clinical strategies.

Defibrillator In the context of AF, a device used to deliver the electrical shock used in electrical cardioversion.

Diagnostic accuracy The degree to which a diagnostic (or screening) tool or procedure is able to distinguish between cases and non-cases. See also 'sensitivity', 'specificity', 'negative predictive value' and 'positive predictive value'.

Diastolic Relating to the phase of the cardiac cycle where the chambers of the heart fill with blood prior to being pumped out during the subsequent systolic phase. See also 'systolic'.

Discounted survival See 'discounting'.

Discounting The process of converting the cost or benefits to be incurred or received at different points in the future to a present value so that they can be compared in commensurate units as if they all occur at the same point in time.

Dominance An intervention is said to dominate an alternative intervention if it is both more effective clinically and less costly.

Drug-eluting stents Special metallic devices which are placed within the coronary artery to reduce the likelihood of coronary stenosis recurring following angioplasty (balloon dilatation of the coronary artery). Drug eluting stents have special drugs within their structure that greatly reduce the recurrence of stenoses.

Dyspnoea Breathlessness.

Echocardiogram An examination of the heart using ultrasound-imaging techniques. An echocardiogram may be performed by placing the ultrasound device across the chest (transthoracic echocardiography), or by inserting it down the gullet to view the heart from behind (transoesophageal echocardiography).

Electrical cardioversion (ECV) See 'cardioversion'.

Electrocardiograph (ECG) A device which traces the electrical activity of the heart by recording the electrical potentials at electrodes placed at various locations around the chest. The recording produced by the electrocardiograph is referred to as an electrocardiogram.

Electrolyte abnormalities Abnormalities or an imbalance in one or more of the body's salts or other chemicals in the blood circulation.

Embolic The passage within the blood stream of a body (eg blood clot), which has formed somewhere and ends up elsewhere within the body (eg brain).

Endpoint In the context of study design, an endpoint is a pre-defined event or events whose occurrence represents the end of follow-up. A composite endpoint is one where more than one event is pre-defined, and the occurrence of any one of them represents the end of follow-up. A primary endpoint is the occurrence of the event, which is the main outcome of interest.

Event-ECG recorder An ECG recording device, which only produces an ECG recording when susceptible electrical activity is detected. It may be triggered automatically or by the patient upon the occurrence of symptoms. See 'cardiomemo'.

Exercise tolerance A measure of a patient's capacity for physical exertion.

Extra cellular fluid volume A term that refers to the fluid bathing the body's cells.

Focal AF AF secondary to a focus of abnormal cells (eg near the pulmonary veins) that can initiate AF.

Functional heart disease Abnormalities of cardiac function – either in systole or diastole.

Good practice point (GPP) Recommended good practice based on the clinical experience of the guideline development group in the absence of robust, published clinical evidence.

Grade (class) of recommendation All recommendations are assigned a grade (A, B, C, D or D(GPP)) according to the level of evidence the recommendation is based on (see 'level of evidence').

Guideline development group (GDG) The guideline development group agrees the clinical questions for the guideline, considers the evidence and develops the recommendations. The GDG membership is multidisciplinary comprising clinicians, patients and/or carers and technical experts.

Haemodynamic function An assessment of cardiac function.

Haemodynamic instability Where cardiac function is compromised so that the patient becomes clinically unstable.

Haemorrhagic death Death caused by a haemorrhagic event such as an intracranial haemorrhage.

Haemorrhagic stroke Stroke secondary to cerebral haemorrhage.

Haemorrhagic transformation The situation where there is bleeding into a (usually large) cerebral infarction, especially in the early phase of a stroke.

Health technology assessment (HTA) These consider the effectiveness, appropriateness and cost of technologies and are funded by the NHS Research and Development Division.

Heart failure See 'congestive heart failure'.

Heart murmur An audible sound with or without a stethoscope, which relates to abnormal flow within the heart or an abnormal communication within the circulatory system.

Heart rate The rate at which the heart performs a complete cycle of coordinated muscular contraction. It is measured in beats per minute (bpm).

Holter monitor An ambulatory ECG recording device.

Hyperadrenergic state Situations where there is abnormal circulating adrenaline (and similar hormones) and/or activation of the sympathetic nervous system eg 'fight or flight' reaction.

Hypertension Abnormally high blood pressure.

Hypotension Abnormally low blood pressure.

Incidence The rate at which an event occurs. Incidence normally measures the rate at which people within a population develop a particular disease or experience other adverse events.

Inconclusive A series of study results are inconclusive when the evidence of different studies do not conflict with each other, but nonetheless lack the strength to be able to reach a definite conclusion.

Incremental cost per QALY The additional cost incurred for each additional QALY. See also 'incremental cost-effectiveness ratio'.

Incremental cost-effectiveness ratio (ICER) A ratio obtained by dividing the incremental costs (cost difference) by the incremental benefits (outcome differences) for two interventions. This depicts the extra cost per unit of outcome. A decision will be made as to whether the additional cost per unit of outcome is worth paying for based on the decision-maker's willingness to pay.

Independent predictor A variable whose value predicts the occurrence of an event independent of the values of other variables.

Infarction An ischaemic lesion. Cerebral infarctions can result in stroke, and myocardial infarctions can result in a heart attack. See also 'myocardial infarction'.

Informed dissent The situation whereby a patient elects to abstain from receiving the optimal therapeutic intervention in the knowledge that this could cause them harm.

Inotropic Drugs that can stimulate the contraction of the heart.

Intention-to-treat analysis (ITT analysis) An analysis of the results of a clinical study in which the data are analysed for all study participants as if they had remained in the group to which they were randomised, regardless of whether or not they remained in the study until the end, crossed over to another treatment or received an alternative intervention.

Intermittent atrial fibrillation AF that is not sustained, but interrupted by periods of sinus rhythm. Intermittent AF is normally considered to apply to more patients than paroxysmal AF, since the periods of sinus rhythm in the former may be very brief and otherwise insignificant.

International normalised ratio (INR) A measure of the clotting ability of blood, usually following use of anticoagulant drugs. It is calculated as the ratio of the length of time it takes blood to clot over the time it would take the blood of a normal subject to clot.

Intracardiac Occurring within the chambers of the heart.

Intracranial haemorrhage A bleeding event within the brain, which may result in a haemorrhagic stroke.

Intubation Being intubated with a transoesophageal breathing tube connected to a mechanical ventilator.

Ischaemic heart disease Heart disease characterised by a reduced supply of blood to the heart. See also 'coronary artery disease'.

Ischaemic stroke Stroke caused by cerebral infarction.

Lacunar infarction Stroke secondary to blockage of the small vessels especially at the border of zones supplied by different arteries.

Left atrial appendage velocity A measurement of the blood flow within the left atrial appendage, usually on TEE.

Left bundle branch block (**LBBB**) A conduction abnormality of the heart due to impaired conduction down the left bundle of His.

Left ventricular dysfunction (**LVD**) Impaired function of the left ventricle.

Left ventricular ejection fraction (**LVEF**) The percentage of blood within the left ventricle that is ejected at each contraction.

Left ventricular end diastolic diameter (**LVEDD**) A measurement of the size of the heart on echo, referring to the internal dimension of the heart in diastole.

Left ventricular end systolic diameter (**LVESD**) A measurement of the size of the heart on echo, referring to the internal dimension of the heart in systole.

Left ventricular hypertrophy (**LVH**) Thickening of the heart muscle, usually secondary to hypertension, aortic valve narrowing etc.

Left ventricular shortening fraction (**LVFS**) A measure of left ventricular function on echo.

Level of evidence A code (eg 1++, 1+, 2++) linked to an individual study, indicating where it fits into the NICE hierarchy of evidence and how well it has adhered to recognised research principles.

Lone AF AF that occurs in the absence of any comorbid cardiovascular disease or other precipitants of AF.

Magnetic resonance imaging (**MRI**) A non-invasive imaging technique allowing detailed examination of the heart.

Management strategy The overarching plan on how to treat a particular patient. In the context of AF, there are two main management strategies – rate control and rhythm control.

Maximum workload A measure of exercise tolerance. See 'exercise tolerance'.

Medically refractory In the context of AF, a patient is medically refractory if successive trials of different drugs and attempts at cardioversion fail to adequately control the symptoms or pathophysiology of AF.

Meta-analysis A statistical technique for combining (pooling) the results of a number of studies that address the same question and report on the same outcomes to produce a summary result. The aim is to derive more precise and clear information from a large data pool. It is generally more reliably likely to confirm or refute a hypothesis than the individual trials.

Methodological limitations Features of the design or reporting of a clinical study which are known to be associated with risk of bias or lack of validity. Where a study is reported in this guideline as having significant methodological limitations, a recommendation has not been directly derived from it.

Mitral annular abnormalities Echo abnormalities of the mitral valve ring/annulus, such as mitral annular calcification.

Mitral regurgitation A backwards flow of blood through the mitral valve normally caused by a dysfunctional mitral valve disease. Mitral regurgitation is classified as 'mild', 'moderate' or 'severe'.

Mitral stenosis An abnormal narrowing of the mitral valve. It can be measured echocardiographically by the mitral valve area.

Mitral valve calcification Deposition of calcium on the mitral valve.

Mitral valve disease Common generic term for disease of the mitral valve.

Mitral valve prolapse Condition where one or more mitral valve leaflets do not appose correctly and there is backward movement of the valve into the atrium, leading to mitral regurgitation.

Mitral valvuloplasty Stretching of the mitral valve, at surgery or using a balloon technique.

Monotherapy In the context of drug therapy, the administration of a single drug for a particular indication.

Multivariate Involving multiple variables. See also 'univariate'.

Myocardial infarction (**MI**) Heart attack.

National Collaborating Centre for Chronic Conditions (**NCC-CC**) A partnership of the Clinical Effectiveness Forum for Allied Health Professions, the NHS Confederation, the Patient Involvement Unit at NICE, the Royal College of General Practitioners, the Royal College of Nursing, the Royal College of Physicians of London, the Royal College of Physicians' Patient and Carers Liaison Committee, the Royal College of Surgeons of England, and the Royal Pharmaceutical Society of Great Britain. Set up in 2000 to undertake commissions from NICE to develop clinical guidelines for the NHS.

National Institute for Health and Clinical Excellence (**NICE**) NICE is the independent organisation responsible for providing national guidance on the promotion of good health and the prevention and treatment of ill health.

National Service Framework (**NSF**) A series of reports recommending service levels and targets for particular disease groups in the UK.

Negative predictive value The proportion of individuals with a negative test result who do not have the disease.

Negative predictor A variable whose values are inversely related to the likelihood of an event occurring.

New York Heart Association (**NYHA**) **Score** A score graded between 1 and 4 that measures cardiac function. Those patients with a score of 4 are considered to have severe heart failure; those with a score of 1 are considered to have asymptomatic or mild heart failure.

Non-significant See 'statistical significance'.

Number needed to treat (**NNT**) The number of patients who must be treated to prevent a single occurrence of the outcome of interest, based on an average calculated from the available data.

Nurse-led cardioversion Practice where the cardioversion procedure is organised, performed and patient follow-up undertaken by specialist nurses.

Odds ratio (**OR**) A measure of treatment effectiveness. The odds of an event happening in the treatment group, expressed as a proportion of the odds of it happening in the control group. The 'odds' is the ratio of non-events to events.

Open-label In the context of study design, a study in which the physicians or investigators are not blinded to which patients are allocated to which treatment arm.

Pacing The situation where a device (a pacemaker) complements or replaces the natural conducting system of the heart.

Palpitations The experience of one's own heartbeat as an awareness of the heart beating or a thumping sensation originating in the chest.

Patent foramen ovale A 'hole in the heart' where there is a congenital connection between the left and right atria.

Percutaneous coronary intervention (**PCI**) Any procedure on the heart undertaken by insertion of a device (eg stent) through a small hole in an artery (eg radial artery, femoral artery).

Peripheral artery disease Atherosclerotic vascular disease involving the peripheral arteries.

Pharmacological cardioversion (**PCV**) See 'cardioversion'.

Pill-in-the-pocket A management strategy for paroxysmal AF involving the patient self-administering antiarrhythmic drugs only upon the onset of an episode of AF.

Platelet-thrombus Blood clot that is rich in platelets rather than fibrin.

Pneumonectomy Removal of whole or part of a lung.

Polypharmacy The administration of multiple drugs for one or more indications.

Pooled analysis The aggregation of patient data from multiple separate studies with the objective of increasing the likelihood of being able to detect significant associations that would otherwise have been missed.

Positive predictive value (**PPV**) The proportion of individuals with a positive test result who actually have the disease.

Precipitant A disease process, toxin, or physiological abnormality which is known to predispose towards development of AF. In many cases, AF precipitants may not be identifiable, in other cases there are identifiable precipitants such as heart failure or alcohol excess.

Pre-excitation syndrome A condition that can predispose to arrhythmia, due to an accessory pathway leading to early/premature excitation of part of the heart. Examples include Wolff–Parkinson–White syndrome and Lown–Ganong–Levine syndrome.

Prevalence The proportion of people within a population who have a particular disease.

Pro-arrhythmic Pre-disposing to the development of cardiac arrhythmias.

Prophylactic Having a preventative action against one or more adverse events.

Pulmonary vein isolation Procedure where ablation is used to create a scar that isolates the tissue of the pulmonary vein from the rest of the heart – thus, if a focus precipitating AF is from within the pulmonary veins, the abnormal electrical impulses cannot reach the heart.

Pulse palpation The act of feeling for, and counting, the pulse.

QT prolongation The prolongation of the QT interval on an electrocardiogram.

Quality of life A measure of a person's overall wellbeing, taking into consideration not only the physical morbidity associated with disease, but also how this detrimentally effects social and psychological functioning.

Quality-adjusted life-year (QALY) An index of survival that is adjusted to account for the patient's quality of life during this time. QALYs have the advantage of incorporating changes in both quantity (longevity/mortality) and quality (morbidity, psychological, functional, social and other factors) of life. Used to measure benefits in cost–utility analysis.

Randomised controlled trial (RCT) A comparative study in which participants are randomly allocated to intervention and control groups and followed up to examine differences in outcomes between the groups.

Rapid atrial fibrillation AF that is associated with a very fast heart beat.

Rate control The attempt to treat AF not through the restoration of sinus rhythm, but through the control of the ventricular rate and the management of stroke risk. See also 'rhythm control'.

Regression equation An equation that assigns weights (co-efficients) to different variables according to the degree to which they are able to predict the occurrence of a particular event or value.

Relative risk (RR) The number of times more likely or less likely an event is to happen in one group compared with another (calculated as the risk of the event in group A, divided by the risk of the event in group B).

Relative risk reduction (RRR) The percentage reduction in the relative risk gained by a particular therapeutic intervention in comparison to another. See also 'relative risk'.

Rhythm control The attempt to treat AF through the restoration and maintenance of sinus rhythm and the management of stroke risk. See also 'rate control'.

Right bundle branch block (RBBB) A conduction abnormality of the heart due to impaired conduction down the right bundle of His.

Risk stratification The process of allocating patients to different levels of risk of an adverse event occurring, based on their clinical or other characteristics.

Self-management In the context of anticoagulation, the process of the patient testing their own blood and making dose-adjustments where necessary.

Self-testing In the context of anticoagulation, the process of the patient testing their own blood and their treating physician recommending dose-adjustments where necessary.

Sensitivity The proportion of individuals classified as positive by the gold or reference standard, who are correctly identified by the study test.

Sensitivity analysis A technique used in economic evaluation or decision analysis to determine how and/or whether plausible changes in uncertain clinical or costing variables affect the main results of the analysis.

Side effect An adverse event that occurs because of a therapeutic intervention.

Significant association See 'statistical significance'.

Significant difference See 'statistical significance'.

Sinus rhythm The normal pattern of electrical activity (and subsequent muscular contraction) of the heart.

Specificity The proportion of individuals classified as negative by the gold (or reference) standard, who are correctly identified by the study test.

Spontaneous cardioversion The process of cardioversion that occurs in the absence of any therapeutic interventions.

Spontaneous echo contrast Smoke-like appearance within the chambers of the heart – usually on TOE – which indicates stasis of blood within the chamber.

Statistical significance A statistical association or difference between two or more variables that has less than a 5% chance of happening through the random concatenation of events is considered to be statistically significant.

Structural heart disease The presence of abnormalities of the heart valves, muscle, chambers etc.

Sudden cardiac death syndrome The condition whereby a patient dies suddenly and unexpectedly with no obvious precipitants.

Supervised management In the context of anticoagulation management, supervised management refers to the situation where a clinician determines any dose adjustments and takes blood measurements.

Supraventricular Pertaining to the atria, eg supraventricular arrhythmia is an abnormal heart rhythm originating in the atria.

Systematic review Research that summarises the evidence on a clearly formulated question according to a pre-defined protocol using systematic and explicit methods to identify, select and appraise relevant studies, and to extract, collate and report their findings. It may or may not use statistical meta-analysis.

Systemic emboli Emboli that has reached the systemic circulation, potentially causing a systemic embolism. See 'embolic'.

Systolic Relating to the phase of contraction of the chambers of the heart during which they eject blood following the diastolic phase. See also 'diastolic'.

Tachycardia-induced cardiomyopathy A form of cardiomyopathy (damage to the heart muscle cells) caused by an excessive heart rate.

Temporal pattern The pattern distinguishing between different subtypes of AF.

Thromboembolic stroke Thrombus that has travelled to the brain circulating leading to blockage of an artery and causing a stroke. See 'embolic', 'stroke'.

Thromboembolism The embolisation (disloading and transportation in the blood) of a thrombus.

Thromboprophylaxis The administration of antithrombotic therapy (anticoagulation, antiplatelet therapy) for the prevention of thrombus formation.

Thrombus Blood clot.

Thyrotoxicosis A disease caused by the hyperactivity of the thyroid glands.

TOE-guided cardioversion In the context of cardioversion, the management of peri-cardioversion thromboembolic risk through the use of transoesophageal echocardiography (TOE) to screen for intracardiac thrombi alongside parenteral anticoagulation. See also 'conventional anticoagulation'.

Torsades de pointes A type of ventricular arrhythmia, which is a polymorphic ventricular tachycardia characterised by 'twisting of points' and commonly associated with a prolonged QT interval on the ECG.

Transoesphageal echocardiography See 'echocardiogram'.

Transient ischaemic attack An ischaemic cerebral event which does not result in any disability or cognitive impairment beyond 24 hours.

Transthoracic echocardiography See 'echocardiogram'.

Treatment failure Failure of the prescribed drug regimen to work. Demonstrated by a lack of clinical improvement or reduction in arrhythmia, etc.

Univariate Pertaining to a single variable. See also 'multivariate'.

Valvular heart disease Diseases of heart valves, eg mitral valve disease.

Vascular death Death caused by a cardiovascular disease or adverse cardiovascular event such as an acute myocardial infarction.

Vascular disease Disease of the vascular system, including both coronary and peripheral blood vessels.

Vaughan-Williams A classification system of antiarrhythmic drugs, depending on whether the drugs activity is as a sodium-channel blocker (Class I), a beta-blocker (Class II), a repolarisation-prolonging agent (Class III), or a calcium-channel blocker (Class IV).

Ventricular arrhythmias Cardiac arrhythmias that originate in the ventricles. See also 'arrhythmia'.

Ventricular rate control See 'rate control'.

Volume loss A term that usually refers to the amount of blood lost.

Wall motion index (WMI) An echocardiographic measure of the contractile function of the ventricles.

Wash-out period A period between the different experimental phases of a crossover study to ensure that no significant traces of previously administered drugs are left in the body to confound the results.

Wolff–Parkinson–White syndrome (WPW) See 'pre-excitation syndrome'.

Appendix F: Stakeholders

The following are registered stakeholders in the development or validation of this guideline:

Black Country Cancer and Cardiac Network

Association of British Healthcare Industries

Association of the British Pharmaceuticals Industry

AstraZeneca UK Ltd

Bard Ltd

Bayer Healthcare Plc

Biotronik UK Ltd

Boehringer Ingelheim Ltd

Boston Scientific Limited

Bristol-Myers Squibb Pharmaceuticals Ltd

Caledonian Medical Ltd

CardioLogic Limited

Guidant Corporation

Johnson & Johnson Medical

Medtronic Limited

Appendix G: Scope

Guideline title

Atrial fibrillation: the management of atrial fibrillation

▷ Short title

Atrial fibrillation

Background

The National Institute for Health and Clinical Excellence (NICE or 'the Institute') has commissioned the National Collaborating Centre for Chronic Conditions to develop a clinical guideline on AF for use in the NHS in England and Wales. This follows referral of the topic by the Department of Health and Welsh Assembly Government (see below). The guideline will provide recommendations for good practice that are based on the best available evidence of clinical and cost effectiveness.

The Institute's clinical guidelines will support the implementation of National Service Frameworks (NSFs) in those aspects of care where a framework has been published. The statements in each NSF reflect the evidence that was used at the time the framework was prepared. The clinical guidelines and technology appraisals published by the Institute after an NSF has been issued will have the effect of updating the framework.

Clinical need for the guideline

Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia. The prevalence of AF increases with age and is the most common arrhythmia causing hospitalisation. In a UK cohort, the prevalence of AF was 8 per 1,000 in males, and 5 per 1,000 in females, with an incidence of 0.9 new cases per 1,000 patient years in males, and 0.2 new cases per 1,000 patient years in females. An increased incidence is associated with age, gender and the presence of other common diseases, including hypertension, heart failure, ischaemic heart disease, diabetes and peripheral artery disease.

AF is associated with a substantial mortality, and with morbidity and hospitalisation from stroke, heart failure, thromboembolism and impaired cognitive function. From a large follow-up study over 40 years, AF was associated with a 1.5 fold (male) to 1.9 fold (female) increased risk of mortality after adjustment for pre-existing cardiovascular disease.

As a common arrhythmia and a cause of substantial morbidity and mortality, AF has considerable implications for healthcare expenditure. Recently, the total cost of AF to the NHS in 2000 (using conservative 1995 prevalence figures) has been calculated to be £459 million or 0.97% of total expenditure. The cost of drug treatment for the year 2000 was estimated to be £69.5 million (including costs for anticoagulation clinic visits) and a further £271.6 million was spent on hospital admissions. These figures do not assume costs for hospitalisations where AF is a secondary diagnosis, or costs of nursing care.

A clinical need for the guideline is justified by the wide variation in management and disagreement amongst UK consultants regarding the best treatment strategies. Furthermore, many patients with AF possess very limited knowledge of AF, its consequences and therapy.

The guideline

The guideline development process is described in detail in two publications which are available from the NICE website (see further information section below). *The guideline development process – an overview for stakeholders, the public and the NHS*[15] describes how organisations can become involved in the development of a guideline. *Guideline development methods – information for national collaborating centres and guideline developers*[16] provides advice on the technical aspects of guideline development.

This document is the scope. It defines exactly what this guideline will (and will not) examine, and what the guideline developers will consider. The scope is based on the referral from the Department of Health and Welsh Assembly Government (see below).

The areas that will be addressed by the guideline are described in the following sections.

Population

▷ Groups that will be covered

The guideline will include people with:

- New onset or acute AF.
- Chronic AF, including paroxysmal (recurrent), persistent and permanent/sustained AF.
- Comorbidities that impact upon AF.
- Postoperative AF.
- Atrial flutter that is indistinguishable from AF in terms of aim of treatment.

▷ Groups that will not be covered

- People under age 18 years.
- Congenital heart disease precipitating AF.

Healthcare setting

Primary and secondary NHS healthcare settings, including referral to tertiary care.

Clinical management

Objectives of management are dependent upon clinical subtype of AF. AF is considered recurrent when a patient develops two or more episodes. These episodes may be paroxysmal if they terminate spontaneously (defined by consensus as 7 days), or persistent (usually more than 7 days) if the arrhythmia requires electrical or pharmacological cardioversion for termination. Successful termination of AF does not alter the classification of persistent AF in these patients. Longstanding AF (defined as more than 1 year) not successfully terminated by cardioversion, or when cardioversion is not pursued, is classified as permanent.

Treatment of acute, sudden onset of AF (with consideration of haemodynamic stability) will be distinguished from treatment of chronic (paroxysmal/recurrent, persistent and permanent) AF. Management of paroxysmal and persistent AF requires control of the rhythm, whilst in permanent AF; the management is generally rate control.

The guideline will include recommendations in the following areas.

▷ Identification of AF

The guideline will not cover general population screening but will include opportunistic case finding.

▷ Diagnosis and assessment criteria

The investigations required for accurate confirmation of a diagnosis of AF and assessment of comorbidity in AF including electrocardiogram (single and 12-lead), 24-hour ECG (or cardiomemo), echocardiogram (including transesophageal), chest X-ray and appropriate haematological and biochemical testing.

▷ Treatment

Treatment as defined for clinical subgroups of paroxysmal, persistent and permanent AF to include the following:

- Prophylactic antithrombotic treatment for the prevention of stroke and thromboembolism, to include antiplatelet and anticoagulation therapy as they specifically relate to AF, and take into account the following:
  - Risk stratification (for example low, medium and high risk) for thromboprophylaxis, including primary and secondary prevention.
  - Different populations (eg acute AF, and peri-stroke).
  - Use of anticoagulation in primary and secondary care setting as supported by the evidence. This includes the potential for management in primary care and self-management using near-patient testing devices.
- Rhythm control including pharmacological (oral and IV) and rhythm self-management ('pill-in-the-pocket') including maintenance of sinus rhythm post conversion.
- Pharmacological rate control (excluding non-pharmacological pacing and ablation, see below) pertaining to monotherapy and combination therapy.
- Efficacy of rate versus rhythm control.
- Selection of patients for referral to specialist services pertaining to non-pharmacological rhythm or rate control (pacing and catheter ablation) and electrophysiological studies.

▷ Review and monitoring

The review and monitoring of AF pertaining to the following:

- The benefits and harms of pharmacological and antithrombotic treatments (eg treatment side effects, and when to stop drug therapy).
- Maintenance of sinus rhythm.
- Patients in whom medical therapy has brought about no response.

Note that guideline recommendations will normally fall within licensed indications; exceptionally, and only where clearly supported by evidence, use outside a licensed indication may be recommended. The guideline will assume that prescribers will use the Summary of Product characteristics to inform their decisions for individual patients.

The following interventions/management will not be included in the guideline:

- Radical therapies that do not form common clinical management will not be addressed, including:
  - Implantable atrial defibrillator (IAD) as the evidence pertains to a selective group of patients and further clinical trials are required.
  - MAZE procedure and other arrhythmia surgery, as well as other novel/experimental non-pharmacological techniques (except for referral for these options).
  - Novel/experimental pharmaceutical antiarrhythmic agents.
- The impact of co-morbidities on AF will be considered but specific treatment of those comorbidities will not be included.
- Generic health problems where the care for people with AF disease does not differ from that of the general population (eg depression).

Status

This is the final scope, which has been through a 4-week period of consultation with stakeholders and has been reviewed by the Institute's independent Guidelines Review Panel.

NICE is in the process of developing the technology appraisal guidance. The AF guideline will signpost these technology appraisals and will consider their role in the treatment of AF.

Implantable cardioverter defibrillators (ICDs) for the treatment of arrhythmias – review of Guidance number 11. Expected date of publication July 2004

Stroke prevention: Ximelagatran in patients with stroke and other thromboembolic complications associated with fibrillation. Expected date of publication February 2006

The development of the guideline recommendations will begin in July 2004.

Further information

Information on the guideline development process is provided in:

The guideline development process – an overview for stakeholders, the public and the NHS[15]

Guideline development methods – information for national collaborating centres and guideline developers.[16]

These booklets are available as PDF files from the NICE website (**www.nice.org.uk**). Information on the progress of the guideline will also be available from the website.

Referral from the Department of Health and Welsh Assembly Government

The Department of Health and Welsh Assembly Government asked the Institute:

'To develop a guideline on the appropriate treatment of atril fibrillation (AF). This should include:

- Identification of patients with AF and appropriate risk assessment tools.
- Diagnosis and assessment.
- Appropriate treatment including:
  - antithrombotic treatment and appropriate use of antiplatelet and anti-coagulation therapy, including advice on potential for management in primary care and self-management using near patient testing devices
  - therapy to control rate of AF
  - medical and electrical cardioversion to control rhythm
  - selection of patients for referral to more specialist services, eg electrophysiological studies, pacing, catheter ablation and, if there is sufficient evidence, the role of ICDs.
- Review and monitoring of condition.'

Which of the following would be the most appropriate treatment option for this patient?

(Please select 1 option)

○	IV diamorphine 10 mg
○	Oral aspirin 600 mg
○	Oral isosorbide mononitrate 30 mg
○	Oxygen 100%
◉	Subcutaneous low molecular weight heparin ✓ Correct

The treatment approach in this patient with acute coronary syndrome is

aspirin 300 mg
try some GTN.

If this fails then

isosorbitdinitrate (ISDN) intravenously
diamorphine (or morphine) 2.5 mg
4 L oxygen and
subcutaneous low molecular weight heparin.

Work Smart Session - MRCP Part 1

Question: 31 of 100

A 67-year-old female is admitted with blackouts.

Her electrocardiogram shows ventricular escape with complete heart block. As you are standing there she blacks out once more. Her rhythm strip shows P wave asystole.

Which of the following would be the initial immediate treatment here after airway and breathing?

(Please select 1 option)

○	Adenosine 6 mg
○	Atropine 0.6 mg
○	Percussion pacing
○	Transcutaneous pacing
○	Transvenous pacing

Submit answer | Skip question | Remove Tag | Remove question

Her electrocardiogram shows ventricular escape with complete heart block. As you are standing there she blacks out once more. Her rhythm strip shows P wave asystole.

Which of the following would be the initial immediate treatment here after airway and breathing?

(Please select 1 option)

○	Adenosine 6 mg
○	Atropine 0.6 mg
◉	Percussion pacing ✓ Correct
○	Transcutaneous pacing
○	Transvenous pacing

Adenosine and atropine are not front line agents in this scenario, particularly adenosine which blocks atrioventricular (AV) conduction; minus one mark if you elected this.

Transvenous pacing is not a fast enough intervention here.

Transcutaneous pacing is the immediate management but percussion pacing may be effective as a holding measure whilst this is instituted.

(Percussion pacing involves gentle thumping of the lower left sternal edge with the fist.)

Time taken: 45 mins 7 secs

Work Smart Session - MRCP Part 1

Question: 32 of 100

A 43-year-old gentleman develops chest pain seven minutes after fibre-optic bronchoscopy.

The procedure had been performed without sedation following an intratracheal injection of 5 ml 2.5% cocaine solution and xylocaine spray to the pharynx for topical anaesthesia.

ECG showed an evolving anterior myocardial infarction.

Which of the following would you prefer for his management?

(Please select 1 option)

○	Beta-blockers
○	Nitrates
○	Percutaneous transluminal coronary angioplasty
○	Thrombolysis with rt-PA
○	Thrombolysis with streptokinase

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Which of the following would you prefer for his management?

(Please select 1 option)

○	Beta-blockers
◉	Nitrates ✓ Correct
○	Percutaneous transluminal coronary angioplasty
○	Thrombolysis with rt-PA
○	Thrombolysis with streptokinase

The underlying mechanism here is vasoconstriction, not thrombosis.

Cocaine is cardiotoxic and its use has been linked to:

- coronary artery spasm
- angina
- myocardial infarction
- arrhythmias
- sudden cardiac death
- myocardial contraction bands, which might act as a substrate for arrhythmias.

It is important to avoid beta-blockers in treating cocaine-induced chest pains or acute myocardial infarctions, as this may result in unopposed 1 adrenergic action with worsening coronary spasm.

Calcium channel antagonists or nitrates should be administered as early as possible.

Work Smart Session - MRCP Part 1

Question: 33 of 100

A 45-year-old man is admitted with central crushing chest pain, sweating and vomiting of one hour duration.

He is conscious with a pulse rate of 100 bpm and a blood pressure of 200/125 mmHg. An ECG shows >2 mm ST elevation in leads I, II, aVL and V2-6.

CBC: normal
U & E: normal
Troponin T: 100 ng/ml

Apart from the presence of xanthelasma (+) there are no other positive findings on clinical examination.

He is given oxygen, aspirin, morphine and intravenous 5 mg atenolol.

What will you do next?

(Please select 1 option)

○	CABG
○	Nitroprusside infusion
○	PTCA
○	Thrombolysis with rt-PA
○	Thrombolysis with streptokinase

Submit answer | Skip question | Tag Question | Remove question

CBC: normal
U & E: normal
Troponin T: 100 ng/ml

Apart from the presence of xanthelasma (+) there are no other positive findings on clinical examination.

He is given oxygen, aspirin, morphine and intravenous 5 mg atenolol.

What will you do next?

(Please select 1 option)

○	CABG
○	Nitroprusside infusion
◉	PTCA ✓ Correct
○	Thrombolysis with rt-PA
○	Thrombolysis with streptokinase

This is a case of acute myocardial infarction.

Typically thrombolysis should be carried out in the absence of any contraindications. BP higher than 200/120 mmHg is one of the contraindications.

So the next appropriate management in this case is urgent angioplasty for extensive anterolateral infarction.

BP control should follow suit.

Work Smart Session - MRCP Part 1

Question: 34 of 100

A 59-year-old male has been discharged from hospital following an uncomplicated admission with myocardial infarction (MI) and treated with stenting. His therapy at discharge included aspirin 75 mg daily, ramipril 10 mg daily, atenolol 50 mg daily and simvastatin 40 mg daily.

On subsequent review, one month after discharge, he is well and unaware of any chest pain. His blood pressure is 134/78 mmHg and he has a resting heart rate of 66 bpm. There are no abnormalities on auscultation of the heart or chest.

Investigations reveal:

Cholesterol	4.6 mmol/l	(<5.2)
Triglyceride	0.8 mmol/l	(0.45-1.69)
Glucose	5.6 mmol/l	(3.0-6.0)
U&E	Normal	

Which of the following therapies added to his current treatment regime would be expected to reduce mortality still further?

(Please select 1 option)

- ○ Amlodipine
- ○ Ezetimibe
- ○ Furosemide
- ○ Omega-3 fatty acids
- ○ Vitamin E

Which of the following therapies added to his current treatment regime would be expected to reduce mortality still further?

(Please select 1 option)

○	Amlodipine
○	Ezetimibe
○	Furosemide
○	Omega-3 fatty acids ← This is the correct answer
◉	Vitamin E ✕ Incorrect answer selected

Of the agents suggested, Omega-3 fatty acids (in essence fish oils) have been demonstrated in the GISSI-prevenzione study to reduce mortality in this particular group of patients with coronary artery disease on standard treatment by a further approximate 20% for all cause mortality and 40% reduction in sudden deaths versus controls.

Vitamin E therapy was associated with no significant differences.

It appears that Omega-3 Fish oils may have a benefit beside improving lipid profile with increases in high density lipoprotein (HDL) and reductions in triglyceride, as it has been suggested that they may confer some anti-arrhythmic effect.

Short-acting calcium antagonists early after MI possibly increase mortality, and certainly have no beneficial effect.

Similarly, furosemide has no data to indicate improved outcome. Ezetimibe, which inhibits cholesterol reabsorption has no data to indicate a survival advantage.

Work Smart Session - MRCP Part 1

Question: 35 of 100

What is troponin?

(Please select 1 option)

○	A component of thick filaments
○	A component of thin filaments
○	A myosin heavy chain
○	A myosin light chain
○	A substance produced by pulmonary vascular endothelium

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 55 mins 17 secs

Question: 35 of 100

What is troponin?

(Please select 1 option)

○	A component of thick filaments
◉	A component of thin filaments ✓ Correct
○	A myosin heavy chain
○	A myosin light chain
○	A substance produced by pulmonary vascular endothelium

Troponin is a component of thin filaments (along with actin and tropomyosin), and is the protein to which calcium binds to accomplish this regulation.

Troponin has three subunits, TnC, TnI, and TnT.

When calcium is bound to specific sites on TnC, the structure of the thin filament changes in such a manner that myosin (a molecular motor organised in muscle thick filaments) attaches to thin filaments and produces force and/or movement.

In the absence of calcium, tropomyosin interferes with this action of myosin, and therefore muscles remain relaxed.

Work Smart Session - MRCP Part 1

Question: 36 of 100

A 29-year-old male is admitted with a one hour history of severe central chest pain associated with vomiting.

It transpires that he used cocaine three hours ago. His blood pressure is 142/74 mmHg and he has a pulse of 110 beats per minute regular. His ECG reveals 3 mm ST segment elevation in leads V2-5.

Which of the following is the most appropriate treatment for this patient?

(Please select 1 option)

○	Abciximab
○	Angiography +/- PTCA
○	Isoket infusion
○	Low molecular weight heparin
○	Tissue plasminogen activator (rtPA)

A 29-year-old male is admitted with a one hour history of severe central chest pain associated with vomiting.

It transpires that he used cocaine three hours ago. His blood pressure is 142/74 mmHg and he has a pulse of 110 beats per minute regular. His ECG reveals 3 mm ST segment elevation in leads V2-5.

Which of the following is the most appropriate treatment for this patient?

(Please select 1 option)

○	Abciximab
◉	Angiography +/- PTCA ✗ Incorrect answer selected
○	Isoket infusion ← This is the correct answer
○	Low molecular weight heparin
○	Tissue plasminogen activator (rtPA)

Cocaine is a drug of widespread abuse and remains one of the commonest causes of acute myocardial infarction (MI) in men below 35 years of age.

The aetiology of cocaine-induced MI is speculated to be related to coronary artery spasm as many patients do not have overt coronary artery disease.

Consequently guidelines suggest the use of nitrates in the first instance coupled with calcium antagonists. If there is no improvement in the clinical condition, then angiography should be considered.

Time taken: 57 mins 2 secs

Work Smart Session - MRCP Part 1

Question: 37 of 100

Which of the following is first to rise following myocardial infarction (MI)?

(Please select 1 option)

○	CK-MB
○	Creatine phosphokinase
○	Lactate dehydrogenase
◉	Myoglobin ✓ Correct
○	Troponin I

Myoglobin, is a sensitive indicator of muscle injury and is first to rise following MI within two hours but is non-specific.

Troponin and CK-MB both begin to rise approximately three hours after MI. Both are far more specific of myocardial injury.

Lactate dehydrogenase (LDH) begins to rise approximately 12 hours after MI.

Work Smart Session - MRCP Part 1

Question: 38 of 100

A 65-year-old is investigated for dyspnoea and is shown to have an ejection fraction of 45% on echocardiography.

How is left ventricular ejection fraction calculated?

(Please select 1 option)

○	Cardiac output/stroke volume
○	End diastolic volume/end systolic volume
○	End diastolic volume/stroke volume
○	End systolic volume/end diastolic volume
○	Stroke volume/end diastolic volume

Submit answer | Skip question | Tag Question | Remove question

Time taken: 57 mins 53 secs

Work Smart Session - MRCP Part 1

Question: 38 of 100

A 65-year-old is investigated for dyspnoea and is shown to have an ejection fraction of 45% on echocardiography.

How is left ventricular ejection fraction calculated?

(Please select 1 option)

◉	Cardiac output/stroke volume ✕ Incorrect answer selected
○	End diastolic volume/end systolic volume
○	End diastolic volume/stroke volume
○	End systolic volume/end diastolic volume
○	Stroke volume/end diastolic volume ← This is the correct answer

The left ventricle pumps only a fraction of the blood it contains.

The ejection fraction is the amount of blood pumped (stroke volume = end diastolic volume - end systolic volume) divided by the amount of blood the ventricle contains (end diastolic volume).

A normal ejection fraction is more than 55% of the blood volume.

Work Smart Session - MRCP Part 1

Question: 39 of 100

Which of the following lipid abnormalities are most likely to be detected in a patient with type 2 diabetes?

(Please select 1 option)

○	Elevated HDL concentrations
○	Elevated LDL concentrations
○	Large buoyant LDL molecules
◉	Reduced triglyceride concentrations ✕ Incorrect answer selected
○	Small dense LDL molecules ← This is the correct answer

In type 2 diabetes increased cholesteryl ester transfer protein (CETP) activity results in the transfer of triglycerides from very low-density lipoprotein (VLDL) to high-density lipoprotein (HDL) and low-density lipoprotein (LDL).

This results in small dense LDL which is more atherogenic being able to be oxidised more readily and penetrate endothelium and macrophages. LDL is not typically elevated in type 2 diabetes although there are qualitative changes as indicated above. HDL is typically low in the patient with type 2 diabetes.

Work Smart Session - MRCP Part 1

Time taken: 6 mins 16 secs

Question: 3 of 100

A 24-year-old woman develops infective endocarditis involving the aortic valve.

She receives a porcine bioprosthesis because of her desire to have children and not to take anticoagulant medication.

After ten years, she must have this prosthetic valve replaced.

Which of the following pathological findings in the bioprosthesis has most likely led to the need for replacement?

(Please select 1 option)

◉	Calcification with stenosis ✓ Correct
○	Dehiscence
○	Infective endocarditis
○	Strut failure
○	Thrombosis

The bioprosthesis has the advantage of not requiring anticoagulation, but it does not wear well with time, and typically must be replaced within five to 10 years.

Work Smart Session - MRCP Part 1

Time taken: 6 mins 16 secs

Question: 4 of 100

A 60-year-old man presents with features of left ventricular failure.

He is comfortable at rest but ordinary physical activity results in fatigue and shortness of breath.

Which of the following New York Heart Association's classifications best match the severity of this man's disease?

(Please select 1 option)

○	Normal
○	NYHA Class I
○	NYHA Class II
○	NYHA Class III
○	NYHA Class IV

Work Smart Session - MRCP Part 1

Question: 40 of 100

A 35-year-old female presents with chest pain on exertion.

On examination she has yellow discolouration of her palmar creases and a diagnosis of remnant hyperlipidaemia (type III hyperlipidaemia) is made.

What is the cause of this hyperlipidaemia?

(Please select 1 option)

- Apo CIII homozygosity
- Apo E-2 homozygosity
- LCAT deficiency
- LDL receptor deficiency
- Lipoprotein lipase deficiency

Submit answer | Skip question | Tag Question | Remove question

- Help

What is the cause of this hyperlipidaemia?

(Please select 1 option)

○	Apo CIII homozygosity
◉	Apo E-2 homozygosity ✓ Correct
○	LCAT deficiency
○	LDL receptor deficiency
○	Lipoprotein lipase deficiency

Remnant hyperlipidaemia is associated with

- hypercholesterolaemia
- hypertriglyceridaemia
- palmar xanthomata
- early onset of cardiovascular disease.

The genotype of the condition is apo E-2/E-2 and occurs with a frequency of 1:100.

Low density lipoprotein (LDL) receptor deficiency is associated with familial hypercholesterolaemia.

Lipoprotein lipase deficiency is rare and associated with marked hypertriglyceridaemia.

Work Smart Session - MRCP Part 1

Question: 41 of 100

A 35-year-old shop worker presents with pain in her calves which develops after 50 yards of walking. The pain settles with rest. On examination she has yellow discolouration of her palmar creases. Her fasting lipid profile reveals:

Cholesterol	9.6mmol/l (<5)
Triglycerides	7.3mmol/l (<2)

What is the likely diagnosis?

(Please select 1 option)

- Chylomicronaemia
- Familial hypercholesterolaemia
- Hypoalphalipoproteinaemia
- Type III hyperlipidaemia
- Type IV hyperlipidaemia

Submit answer | Skip question | Tag Question | Remove question

with rest. On examination she has yellow discolouration of her palmar creases. Her fasting lipid profile reveals:

Cholesterol	9.6mmol/l (<5)
Triglycerides	7.3mmol/l (<2)

What is the likely diagnosis?

(Please select 1 option)

- Chylomicronaemia
- Familial hypercholesterolaemia
- Hypoalphalipoproteinaemia
- Type III hyperlipidaemia ✓ Correct
- Type IV hyperlipidaemia

Remnant hyperlipidaemia (Type III hyperlipidaemia) is associated with elevated fasting cholesterol (usually >7.8mmol/l) and triglyceride levels (usually >5.0mmol/l) It presents with palmar xanthomata and early onset cardiovascular disease (CHD,PVD and CVA). Hypoalphalipoproteinaemia is a rare, familial condition and is associated with low HDL. Chylomicronaemia is associated particularly with hypertriglyceridaemia and not with large elevations in cholesterol. Familial hypercholesterolaemia is due to LDL-receptor deficiency, and is not associated with elevated triglyceride levels.

Work Smart Session - MRCP Part 1

Question: 42 of 100

A 65-year-old man presents with a six month history of deteriorating breathlessness.

He is found to have aortic stenosis.

Which one of the following physical signs provides the best clinical marker of the severity of the valvular disease?

(Please select 1 option)

○	Character of the apex beat
○	Character of the carotid pulse
○	Character of the second heart sound
○	Intensity of the murmur
○	Length of the murmur

Submit answer | Skip question | Tag Question | Remove question

A 65-year-old man presents with a six month history of deteriorating breathlessness.

He is found to have aortic stenosis.

Which one of the following physical signs provides the best clinical marker of the severity of the valvular disease?

(Please select 1 option)

○	Character of the apex beat
○	Character of the carotid pulse
○	Character of the second heart sound
○	Intensity of the murmur
◉	Length of the murmur ✓ Correct

The apex beat in aortic stenosis is not displaced but has a heaving character, the pulse is characteristically of small volume and slow rising, the second heart sound maybe inaudible or paradoxically split.

The murmur tends to become longer as the disease is more severe because of the longer ejection time needed.

The intensity of the murmur is not a good guide to severity as this will become less as the cardiac output is reduced with more severe disease.

Work Smart Session - MRCP Part 1

Question: 43 of 100

A 17-year-old female presents after taking an overdose of her grandmother's medication.

Investigations revealed a serum potassium of 6 mmol/L (3.5-4.9).

Which one of the following drugs is the most likely cause of this abnormality?

(Please select 1 option)

○	Aspirin
○	Digoxin
○	Fluoxetine
○	Omeprazole
○	Propranolol

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 17-year-old female presents after taking an overdose of her grandmother's medication.

Investigations revealed a serum potassium of 6 mmol/L (3.5-4.9).

Which one of the following drugs is the most likely cause of this abnormality?

(Please select 1 option)

○	Aspirin
○	Digoxin
○	Fluoxetine
○	Omeprazole
◉	Propranolol ✓ Correct

Betablockers, particularly propranolol, in overdose can cause hyperkalaemia by transmembrane shifts. It is useful to think of the opposite - beta-agonists such as salbutamol are far more widely known to cause hypokalaemia.

Overdose of digoxin therapy most commonly manifests as rhythm disturbance and may be exacerbated by hyper- or hypokalaemia.

Salicylate overdose causes metabolic acidosis and respiratory alkalosis.

Time taken: 1 hrs 3 mins 34 secs

Work Smart Session - MRCP Part 1

Question: 44 of 100

A 72-year-old man presented following three episodes of transient loss of consciousness not associated with chest pain. There was a previous history of an anterior myocardial infarction.

On examination his blood pressure was 140/80 mmHg and the apex beat was diffuse in character and displaced to the left. There were no neurological signs.

The ECG showed sinus rhythm with occasional ventricular extrasystoles, deep anterior Q waves and ST segment elevation in leads V2 - V6, without reciprocal depression.

Which one of the following would be the most appropriate initial course of action?

(Please select 1 option)

○	Administer tissue plasminogen activator
○	Arrange an electroencephalogram
○	Arrange immediate computerised tomography (CT) brain scan
○	Observe in the coronary care unit
○	Proceed to coronary arteriography

There were no neurological signs.

The ECG showed sinus rhythm with occasional ventricular extrasystoles, deep anterior Q waves and ST segment elevation in leads V2 - V6, without reciprocal depression.

Which one of the following would be the most appropriate initial course of action?

(Please select 1 option)

○	Administer tissue plasminogen activator
○	Arrange an electroencephalogram
○	Arrange immediate computerised tomography (CT) brain scan
◉	Observe in the coronary care unit ✓ Correct
○	Proceed to coronary arteriography

The history suggests that this man has persistent ST elevation in the anterior leads, with a previous history of anterior myocardial infarction due to left ventricular (LV) aneurysm. The blackouts are cardiac syncope due to rhythm disturbance. An ECHO would quickly support the diagnosis but, because of the risk of sudden death, observation on CCU is required.

The loss of consciousness is likely to be due to recurrent arrhythmic episodes or vertebrobasilar transient ischaemic attacks (TIAs), as a result of embolisation of an LV thrombus.

The most important investigation for this patient whom you suspect has arrhythmic episodes would be telemetry/24 hour monitoring, and hence observation on the coronary care unit (CCU) is appropriate.

Work Smart Session - MRCP Part 1

Question: 45 of 100

A 74-year-old man presented with intermittent chest pain at rest.

Which one of the following would most strongly suggest that the pain was due to myocardial ischaemia?

(Please select 1 option)

- Associated dyspnoea
- Coexistent claudication
- Past history of cigarette smoking
- Radiation of pain to the jaw
- Relief of pain by sublingual nitrate

Submit answer | Skip question | Tag Question | Remove question

Question: 45 of 100

A 74-year-old man presented with intermittent chest pain at rest.

Which one of the following would most strongly suggest that the pain was due to myocardial ischaemia?

(Please select 1 option)

○	Associated dyspnoea
○	Coexistent claudication
○	Past history of cigarette smoking
○	Radiation of pain to the jaw ← This is the correct answer
◉	Relief of pain by sublingual nitrate ✕ Incorrect answer selected

Nitrates may relieve the pain of oesophageal spasm, as well as that of myocardial ischaemia.

Associated dyspnoea may be due to anxiety.

Coexistent claudication suggests the presence of peripheral vascular disease.

A past history of cigarette smoking is a risk factor for the development of cardiovascular disease.

However, the most specific feature of the given options which suggests that the pain is myocardial ischaemia, is the radiation to the jaw, which is relatively specific for pain of myocardial ischaemia.

Work Smart Session - MRCP Part 1

Question: 46 of 100

A 55-year-old male presents with dysphagia, retrosternal discomfort and weight loss. Studies reveal achalasia.

Which of the following is most likely to provide symptomatic relief?

(Please select 1 option)

○	Buscopan
○	Diazepam
○	Nifedipine
○	Omeprazole
○	Surgical cardiomyotomy

Submit answer | Skip question | Tag Question | Remove question

Question: 46 of 100

A 55-year-old male presents with dysphagia, retrosternal discomfort and weight loss. Studies reveal achalasia.

Which of the following is most likely to provide symptomatic relief?

(Please select 1 option)

○	Buscopan
○	Diazepam
○	Nifedipine
○	Omeprazole
◉	Surgical cardiomyotomy ✓ Correct

75% cure may be expected by cardiomyotomy in achalasia. Nitrates and hydralazine can help in the short term. None of other choices help the symptoms.

Oesophageal dilatation is usually attempted before laparoscopic surgical myotomy.

Time taken: 1 hrs 6 mins 58 secs

Work Smart Session - MRCP Part 1

Question: 47 of 100

A 74-year-old woman with longstanding hypertension and rheumatoid arthritis presented with dyspnoea.

On examination she was in atrial fibrillation and was normotensive. The jugular venous pressure (JVP) was elevated. She had bilateral pitting lower limb oedema and ascites. Her echocardiogram showed normal left ventricular systolic function and bi-atrial enlargement.

What is the most likely diagnosis?

(Please select 1 option)

- ○ Constrictive pericarditis
- ○ Hypertensive heart disease
- ○ Hypothyroidism
- ○ Lymphatic obstruction
- ○ Pulmonary fibrosis

Submit answer | Skip question | Tag Question | Remove question

(Please select 1 option)

◉	Constrictive pericarditis ✓ Correct
○	Hypertensive heart disease
○	Hypothyroidism
○	Lymphatic obstruction
○	Pulmonary fibrosis

The combination of:

- shortness of breath
- atrial fibrillation
- lower limb oedema
- ascites
- raised JVP
- bi-atrial enlargement with normal systolic ventricular function

is typical of constrictive pericarditis.

Hypertension is another cause of diastolic dysfunction but this lady is normotensive and hypertension would not create such dramatic clinical signs.

Further ECHO examination would reveal peak systolic and diastolic values decreasing with inspiration, and impaired diastolic function.

Constrictive pericarditis is associated with rheumatoid arthritis, and can be a difficult clinical diagnosis.

Time taken: 1 hrs 8 mins 53 secs

Work Smart Session - MRCP Part 1

Question: 48 of 100

A 55-year old man presented with angina pectoris.

His pain was relieved by buccal glyceryl trinitrate (GTN) 5 mg. His discharge medication was isosorbide mononitrate (ISMN) 20 mg BD.

Which factor accounts for the dose difference between these two formulations?

(Please select 1 option)

○	Absorption
○	First pass metabolism
○	Lipid solubility
○	Phase II (conjugation) metabolism
○	Plasma clearance

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Which factor accounts for the dose difference between these two formulations?

(Please select 1 option)

○	Absorption ← This is the correct answer
◉	First pass metabolism ✕ Incorrect answer selected
○	Lipid solubility
○	Phase II (conjugation) metabolism
○	Plasma clearance

Buccal GTN is quickly converted to di- and mono-nitrates which have half-lives of two hours. Its effective duration of action is 30 minutes. It is metabolised by the liver to inorganic nitrite.

ISMN is not subject to first pass metabolism in the liver. The overall half-life of isosorbide mononitrate is about five hours, and that of GTN is two hours. Thus, this would result in a reduced dose of ISMN being required if related to plasma clearance.

The sublingual route (which avoids first pass effect and the need for gastrointestinal absorption) is the preferred route for achieving therapeutic effect quickly, as GTN is absorbed efficiently by this route. However, the total dose administered by this route must be limited to avoid excessive effects.

When a much longer duration is needed, oral preparations can be given that contain a sufficient amount of drug to result in sustained systemic blood levels.

Time taken: 1 hrs 10 mins 9 secs

Work Smart Session - MRCP Part 1

Question: 49 of 100

A 29-year-old female presents with acute right-sided weakness.

She has one child aged four years and had two spontaneous abortions in the past. After the birth of her child she developed a DVT and required three months' anticoagulation with warfarin.

Examination revealed a right hemiparesis. A CT head scan showed a left middle cerebral artery territory infarct.

What is the most likely finding on echocardiography?

(Please select 1 option)

○	Atrial septal defect
○	Bicuspid aortic valve
○	Left atrial myxoma
○	Normal appearances
○	Ventricular septal defect

Submit answer | Skip question | Tag Question | Remove question

She has one child aged four years and had two spontaneous abortions in the past. After the birth of her child she developed a DVT and required three months' anticoagulation with warfarin.

Examination revealed a right hemiparesis. A CT head scan showed a left middle cerebral artery territory infarct.

What is the most likely finding on echocardiography?

(Please select 1 option)

○	Atrial septal defect
○	Bicuspid aortic valve
○	Left atrial myxoma
◉	Normal appearances ✓ Correct
○	Ventricular septal defect

This patient has a prothrombotic tendency suggestive of the lupus anticoagulant with recurrent abortions, previous deep vein thrombosis (DVT) and now she has developed a left hemiparesis.

This has occurred off warfarin and it is highly unlikely to be due to any right to left transference of clot.

It is more likely to be due to spontaneous infarct related to the thrombophilia and her heart is likely to be normal.

Which of the following New York Heart Association's classifications best match the severity of this man's disease?

(Please select 1 option)

○	Normal
○	NYHA Class I
○	NYHA Class II ← This is the correct answer
◉	NYHA Class III ✕ Incorrect answer selected
○	NYHA Class IV

In 1928 the New York Heart Association published a classification of patients with cardiac disease based on clinical severity and prognosis.

This classification has been updated in seven subsequent editions of Nomenclature and Criteria for Diagnosis of Diseases of the Heart and Great Vessels (Little, Brown & Co). The ninth edition, revised by the Criteria Committee of the American Heart Association, New York City Affiliate, was released March 4, 1994.

"Class II. Patients with cardiac disease resulting in slight limitation of physical activity. They are comfortable at rest. Ordinary physical activity results in fatigue, palpitation, dyspnea or anginal pain."

Further reading:
Classification of Functional Capacity and Objective Assessment American Heart Association

Work Smart Session - MRCP Part 1

Question: 50 of 100

A 57-year-old female school cleaner is undergoing investigation for breathlessness.

Which of the following is NOT in keeping with a diagnosis of constrictive pericarditis?

(Please select 1 option)

○	Ascites
○	Elevated JVP with absent y descent
○	Orthopnoea
○	Peripheral oedema
○	Previous cardiac surgery

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

(Please select 1 option)

○	Ascites
○	Elevated JVP with absent y descent ← This is the correct answer
○	Orthopnoea
○	Peripheral oedema
◉	Previous cardiac surgery ✕ Incorrect answer selected

Constrictive pericarditis typically impedes late diastolic ventricular filling, which produces an elevated jugular venous pressure (JVP), with prominent x and y descent.

Pulsus paradoxus is a variable finding, unless a pericardial effusion with an abnormally elevated pressure exists.

Other signs include:

- oedema
- ascites
- hepatomegaly
- orthopnoea
- dyspnoea.

Constrictive pericarditis may be a subtle cause of dyspnoea after cardiac surgery.

Question: 51 of 100

Which of the following is NOT associated with left atrial myxoma?

(Please select 1 option)

○	Adrenal hyperplasia
○	A mid systolic click
○	Left atrial dilatation
○	Sudden death
○	Systemic emboli

Submit answer | Skip question | Tag Question | Remove question

Which of the following is NOT associated with left atrial myxoma?

(Please select 1 option)

◉	Adrenal hyperplasia ✕ Incorrect answer selected
○	A mid systolic click ← This is the correct answer
○	Left atrial dilatation
○	Sudden death
○	Systemic emboli

Atrial myxoma in the heart make up 50% of primary cardiac tumours.

They are most common in the left atrium arising from a pedicle on the fossa ovalis. One third present with emboli, a third with systemic inflammation (erythrocyte sedimentation rate [ESR] elevated in 1/3) and a third are asymptomatic when detected.

They can intermittently flop through the mitral valve, and cause a mid-diastolic click (tumour plop) when they stop moving.

Elevated left atrial pressures cause dilatation. Syncope can occur due to obstruction. They are more common in women.

Carney complex is a familial multiple neoplasia and lentiginosis syndrome, associated with

- primary adrenal hypercortisolism
- lentigines and naevi of the skin
- various tumours including myxoma.

Question: 52 of 100

Which of the following statements regarding B-type natriuretic peptide (BNP), is correct?

(Please select 1 option)

○	BNP augments sodium reabsorption in the kidney
○	BNP causes arterial and venous smooth muscle vasodilatation
○	BNP is synthesised predominantly in the cerebrovascular circulation
○	BNP synthesis is decreased by thyroid hormone
○	The stimulus for BNP release is increased ventricular pressure load

Submit answer | Skip question | Tag Question | Remove question

Which of the following statements regarding B-type natriuretic peptide (BNP), is correct?

(Please select 1 option)

○	BNP augments sodium reabsorption in the kidney
◉	BNP causes arterial and venous smooth muscle vasodilatation ✓ Correct
○	BNP is synthesised predominantly in the cerebrovascular circulation
○	BNP synthesis is decreased by thyroid hormone
○	The stimulus for BNP release is increased ventricular pressure load

The ventricular myocardium is the primary site of BNP synthesis.

The stimulus for BNP release is myocyte stretch, rather than transmural pressure load.

BNP synthesis is increased by thyroid hormones as well as glucocorticoids, endothelin-1, angiotensin-II and tachycardia, independent of the haemodynamic effects of these factors.

In the kidney, BNP causes increased glomerular filtration rate (GFR) and inhibition of sodium reabsorption, leading to natriuresis and diuresis.

BNP leads to reduced blood pressure, and reduced pre-load due to relaxing effects on vascular smooth muscle.

For an informative review refer to Lancet 2003;362:316-22.

Work Smart Session - MRCP Part 1

Question: 53 of 100

A 69-year-old woman presented with an ulcer over the left ankle, which had developed over the previous nine months. She had a history of right deep vein thrombosis (DVT) five years previously.

On examination she had a superficial slough-based ulcer, 6 cm in diameter, over the medial malleolus with no evidence of cellulitis.

Which one of the following is the most appropriate next investigation?

(Please select 1 option)

○	Ankle-brachial pressure index
○	Bacteriological swab of the ulcer
○	Bilateral lower limb arteriogram
○	Right leg venogram
○	Venous duplex ultrasound scan

Submit answer | Skip question | Tag Question | Remove question

- Help

Which one of the following is the most appropriate next investigation?

(Please select 1 option)

◉	Ankle-brachial pressure index ✓ Correct
○	Bacteriological swab of the ulcer
○	Bilateral lower limb arteriogram
○	Right leg venogram
○	Venous duplex ultrasound scan

It has been reported that venous ulcerations are the most common type of ulcer affecting the lower extremities. The probable underlying cause of venous congestion, which may promote ulceration, is venous insufficiency.

The treatment of venous ulceration is control of oedema, treating any infection, and compression. However, compressive dressings or devices should not be applied if the arterial circulation is impaired.

It is thus important to identify any arterial disease, and ankle-brachial pressure index is a simple way of doing this. One may then progress to lower limb arteriogram if indicated.

There is no clinical sign of infection, and although a bacterial swab would help to rule out pathogens within the ulcer, arterial insufficiency is the more important issue.

If there is a clinical suspicion of DVT then duplex (or rarely a venogram) is indicated to decide on the indication for warfarin.

Question: 54 of 100

A 70-year-old woman is referred with hypertension.

Despite lifestyle advice, her GP notes blood pressure recordings averaging 170/100 mmHg. She was commenced on an antihypertensive but one month later complains of symptoms suggestive of postural hypotension.

Which one of the following is most likely to be responsible for this side effect?

(Please select 1 option)

○	Amlodipine
○	Atenolol
○	Bendroflumethiazide
○	Doxazosin
○	Lisinopril

Submit answer | Skip question | Tag Question | Remove question

Despite lifestyle advice, her GP notes blood pressure recordings averaging 170/100 mmHg. She was commenced on an antihypertensive but one month later complains of symptoms suggestive of postural hypotension.

Which one of the following is most likely to be responsible for this side effect?

(Please select 1 option)

○	Amlodipine
○	Atenolol ← This is the correct answer
◉	Bendroflumethiazide ✕ Incorrect answer selected
○	Doxazosin
○	Lisinopril

This is an odd question, as all the agents can cause postural hypotension, but one might think that the causative agent would be an alpha-blocker. However, the evidence suggests the contrary, as amongst all the classes a beta-blocker is most associated with postural hypotension in the elderly.

So, the correct answer is a beta-blocker, yet it is a lottery to determine if the RCP would have this down as their right answer.

Other agents particularly associated with postural hypotension include the centrally acting agents, like alpha methyldopa and reserpine.

Work Smart Session - MRCP Part 1

Question: 55 of 100

A paper describes a new diagnostic test for myocardial infarction (MI).

You want to know what proportion of patients, who are classified as not having had a myocardial infarction by the test, will actually not have had a myocardial infarction.

Which one of the following measurements would indicate this?

(Please select 1 option)

○	Accuracy
○	Negative predictive value
○	Positive predictive value
○	Sensitivity
○	Specificity

Submit answer | Skip question | Tag Question | Remove question

You want to know what proportion of patients, who are classified as not having had a myocardial infarction by the test, will actually not have had a myocardial infarction.

Which one of the following measurements would indicate this?

(Please select 1 option)

○	Accuracy
○	Negative predictive value ← This is the correct answer
○	Positive predictive value
○	Sensitivity
◉	Specificity ✕ Incorrect answer selected

The proportion of 'true negatives' not having had a MI correctly identified by this test is called the negative predictive value and refers to the number accurately identified not to have MI by the new test over the number without MI identified by the test + those wrongly identified as not having had an MI.

Specificity is the number without MI accurately predicted.

Sensitivity refers to the number correctly identified with MI by the new test.

A positive predictive value refers to the number accurately identified with MI by the test over the number accurately identified with MI + those wrongly identified with MI.

Question: 56 of 100

A 60-year-old man takes atenolol for hypertension.

Which of the following side effects is he most likely to be aware of two hours after taking atenolol?

(Please select 1 option)

○	Fatigue
○	Hesitancy of micturition
○	Nausea
○	Orthostatic hypotension
○	Somnolence

Question: 56 of 100

A 60-year-old man takes atenolol for hypertension.

Which of the following side effects is he most likely to be aware of two hours after taking atenolol?

(Please select 1 option)

◉	Fatigue ✓ Correct
○	Hesitancy of micturition
○	Nausea
○	Orthostatic hypotension
○	Somnolence

Atenolol is a water soluble beta-blocker, taken once daily and is not associated with drowsiness/sleep disturbance like the lipid -soluble beta-blockers.

It is not associated with nausea or hesitancy of micturition and would be unlikely to produce significant postural hypotension in a hypertensive subject.

However, fatigue is a frequent side effect which typically is felt two hours and beyond after taking the drug.

Work Smart Session - MRCP Part 1

Question: 57 of 100

A 34-year-old man presented for an insurance medical. He was symptom free, but clinical examination suggested a small ventricular septal defect (VSD).

Which one of the following findings was most likely to have been present?

(Please select 1 option)

○	An early diastolic murmur
○	A short systolic murmur at the left sternal edge
○	A systolic murmur maximal at the apex
○	A systolic murmur with thrill at the left sternal edge (LSE)
○	Fixed splitting of the second heart sound

Work Smart Session - MRCP Part 1

Question: 57 of 100

A 34-year-old man presented for an insurance medical. He was symptom free, but clinical examination suggested a small ventricular septal defect (VSD).

Which one of the following findings was most likely to have been present?

(Please select 1 option)

○	An early diastolic murmur
◉	A short systolic murmur at the left sternal edge ✕ Incorrect answer selected
○	A systolic murmur maximal at the apex
○	A systolic murmur with thrill at the left sternal edge (LSE) ← This is the correct answer
○	Fixed splitting of the second heart sound

Typically, a small VSD generates a pansystolic murmur at the LSE accompanied by a thrill. The murmur may be heard at the apex but is usually loudest at the LSE.

Very small defects may generate an early/late systolic murmur.

Fixed splitting of the heart sounds usually accompanies atrial septal defects.

Work Smart Session - MRCP Part 1

Question: 58 of 100

You are asked to see a patient in the intensive care unit who is short of breath and tachycardic to rule out a cardiac cause of her symptoms.

A right heart catheter reveals that the mixed venous O_2 saturation is 70%; the pulmonary capillary wedge O_2 saturation is 97%. The haemoglobin is normal and the patient is afebrile.

Which of the following is the most appropriate statement that could be applied to her features?

(Please select 1 option)

○	Her cardiac output is decreased
○	Her cardiac output is normal
○	Her heart is normal
○	She has high-output failure
○	She is in shock due to a non-cardiac cause

Submit answer | Skip question | Remove question

You are asked to see a patient in the intensive care unit who is short of breath and tachycardic to rule out a cardiac cause of her symptoms.

A right heart catheter reveals that the mixed venous O_2 saturation is 70%; the pulmonary capillary wedge O_2 saturation is 97%. The haemoglobin is normal and the patient is afebrile.

Which of the following is the most appropriate statement that could be applied to her features?

(Please select 1 option)

○	Her cardiac output is decreased
○	Her cardiac output is normal ← This is the correct answer
◉	Her heart is normal ✕ Incorrect answer selected
○	She has high-output failure
○	She is in shock due to a non-cardiac cause

The right heart and wedge catheters show normal saturations, the latter suggesting that she has good pulmonary oxygenation and so these features would argue against any failure.

Decreased or high output failure would certainly argue against shock of any sort; therefore, one cannot go as far as to say that she has a normal heart, so the best response (by a process of elimination) is that she has a normal output.

Question: 59 of 100

Angina due to an imbalance between O_2 supply and demand without atherosclerosis would most likely be seen in which of the following circumstances?

(Please select 1 option)

◉	Aortic regurgitation ✓ Correct
○	Cardiac tamponade
○	Pulmonary regurgitation
○	Right heart failure
○	Tricuspid regurgitation

Non-atherosclerotic angina would be associated with conditions such as:

- thyrotoxicosis
- aortic regurgitation
- aortic stenosis
- hypertrophic cardiomyopathy
- anaemia

to name but a few.

(Please select 1 option)

○	CACNA1c gene
○	Caveolin 3 related gene
◉	Human ether-à-go-go related gene (hERG) ✗ Incorrect answer selected
○	KCNQ1 gene ← This is the correct answer
○	SCN5A gene

Mutations in the KCNE1 and KCNQ1 genes cause Jervell and Lange-Nielsen syndrome.

The KCNE1 and KCNQ1 genes provide instructions for making proteins that work together to form a channel across cell membranes. These channels transport positively charged potassium atoms (ions) out of cells. The movement of potassium ions through these channels is critical for maintaining the normal functions of inner ear structures and cardiac muscle.

All the other genes mentioned are associated with long QT syndromes.

The human ether-à-go-go related gene (hERG) is the gene affected by drugs that lengthen QT interval inadvertently; erythromycin, terfenadine, and ketoconazole.

Question: 6 of 100

A 55-year-old man is being treated for hyperlipidaemia with atorvastatin 40 mg nocte.

He has a history of ischaemic heart disease.

His fasting lipids show:

Total cholesterol	3.8 mmol/l	(<5.2)
Triglycerides	1.3 mmol/l	(0.5-1.7)
LDL-cholesterol	1.9 mmol/l	(<2.6)
HDL-cholesterol	0.7 mmol/l	(0.7-1.7)

Which of the following changes of treatment would be expected to raise his HDL cholesterol level by the greatest amount?

(Please select 1 option)

- Add cholestyramine
- Add ezetimibe
- Add fenofibrate
- Add nicotinic acid
- Switch atorvastatin to rosuvastatin

Question: 61 of 100

A 60-year-old man's echocardiogram shows a dilated left ventricular (LV) cavity with the remainder of the other chamber sizes normal.

Which of the following is the most likely diagnosis?

(Please select 1 option)

○	Aortic regurgitation (AR) ← This is the correct answer
○	Aortic stenosis (AS)
◉	Hypertensive heart disease ✕ Incorrect answer selected
○	Mitral regurgitation (MR)
○	Mitral stenosis (MS)

No echocardiographic data are provided regarding the valves, but a volume overload as with AR would result in dilatation of the left ventricle.

MR, AS, and hypertension would have the effect of causing hypertrophy and a smaller LV cavity.

MS would have little effect on LV dimensions.

Which of the following is NOT typical of acute aortic regurgitation?

(Please select 1 option)

○	Decrescendo diastolic murmur
○	Hypotension
○	Mitral valve pre-closure
○	Normal cardiac output
◉	Peripheral vasodilatation ✓ Correct

Findings that would be typical include:

- Large pulse volume
- Increased pulse pressure
- A decrescendo murmur
- A low diastolic blood pressure.

Vasoconstriction not dilatation is typically found.

Work Smart Session - MRCP Part 1

Question: 64 of 100

Which of the following is true regarding the coronary circulation?

(Please select 1 option)

○	Adenosine is an important mediator of metabolic vasodilatation
○	Coronary blood flow is independent of myocardial oxygen consumption due to autoregulation
○	Coronary blood flow within a normal range of blood pressure is primarily determined by perfusion pressure
○	Increased myocardial O_2 demand is met primarily by increasing O_2 extraction
○	The vasodilatory reserve of the epicardium and endocardium is equivalent under normal physiologic conditions

Submit answer | Skip question | Tag Question | Remove question

Time taken: 1 hrs 41 mins 23 secs

Work Smart Session - MRCP Part 1

Question: 64 of 100

Which of the following is true regarding the coronary circulation?

(Please select 1 option)

○	Adenosine is an important mediator of metabolic vasodilatation ← This is the correct answer
○	Coronary blood flow is independent of myocardial oxygen consumption due to autoregulation
○	Coronary blood flow within a normal range of blood pressure is primarily determined by perfusion pressure
◉	Increased myocardial O_2 demand is met primarily by increasing O_2 extraction ✕ Incorrect answer selected
○	The vasodilatory reserve of the epicardium and endocardium is equivalent under normal physiologic conditions

Adenosine has a particularly short half life, acts on specific adenosine cell surface receptors (A1 and A2) and is inactivated by adenosine deaminase. It results in coronary vasodilatation and depression of sinus node automaticity and AVN conduction.

Coronary blood flow is dependent on myocardial oxygen consumption and is pretty independently maintained throughout the ranges of blood pressure.

Increasing O_2 demands are met by increased blood supply facilitated by vasodilatation brought about by adenosine production.

Work Smart Session - MRCP Part 1

Question: 65 of 100

Which of the following findings is the most specific for a diagnosis of myocardial infarction?

(Please select 1 option)

○	An akinetic area of LV wall motion on ECHO
○	Elevated cardiac enzymes
◉	Evolution of Q waves on ECG ✓ Correct
○	History of severe chest pain
○	ST elevation on ECG

Cardiac enzymes may be elevated in pulmonary embolism (PE), renal failure and raised ST segments associated with pericarditis.

Akinetic wall motion on the echo may occur with any regional disease process like amyloid, etc.

The evolution of Q waves is the most suggestive of an infarct.

Work Smart Session - MRCP Part 1

Question: 66 of 100

In a patient presenting with aortic stenosis (AS), which of the following findings would be most helpful in establishing a diagnosis of congenital bicuspid valve as the aetiology?

(Please select 1 option)

○	Age
○	Calcified leaflets
○	Commissural fusion on ECHO
○	Negative history for rheumatic fever
○	Systolic ejection click

Submit answer | Skip question | Tag Question | Remove question

Time taken: 1 hrs 44 mins 29 secs

Work Smart Session - MRCP Part 1

Question: 66 of 100

In a patient presenting with aortic stenosis (AS), which of the following findings would be most helpful in establishing a diagnosis of congenital bicuspid valve as the aetiology?

(Please select 1 option)

○	Age
○	Calcified leaflets
◉	Commissural fusion on ECHO ✕ Incorrect answer selected
○	Negative history for rheumatic fever
○	Systolic ejection click ← This is the correct answer

Age and calcified aortic root suggest calcific aortic valvular disease.

Rheumatic AS results from fibrosis of the leaflets and fusion of the commissures.

An ejection click or ejection sound, best heard at the apex, implies that the site of the stenosis is mostly valvular and of congenital origin, that is, bicuspid valvular disease.

Question: 68 of 100

A 68-year-old man has been very ill for months following the onset of chronic liver disease with hepatitis C infection.

He experiences a sudden loss of consciousness and then exhibits hemiplegia on the right. A cerebral angiogram reveals lack of perfusion in the left middle cerebral artery distribution.

What is the most likely cardiac lesion to be associated with this finding?

(Please select 1 option)

○	Acute rheumatic fever
○	Left atrial myxoma
○	Libman-Sacks endocarditis
○	Non-bacterial thrombotic endocarditis
○	Paradoxical thromboembolus

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Question: 68 of 100

A 68-year-old man has been very ill for months following the onset of chronic liver disease with hepatitis C infection.

He experiences a sudden loss of consciousness and then exhibits hemiplegia on the right. A cerebral angiogram reveals lack of perfusion in the left middle cerebral artery distribution.

What is the most likely cardiac lesion to be associated with this finding?

(Please select 1 option)

○	Acute rheumatic fever
○	Left atrial myxoma
○	Libman-Sacks endocarditis
◉	Non-bacterial thrombotic endocarditis ✓ Correct
○	Paradoxical thromboembolus

Marantic endocarditis has platelet-fibrin thrombi that are prone to embolising.

This form of non-infective endocarditis can be seen in persons who are very debilitated or who have a hypercoagulable state.

A 35-year-old healthy woman has a faint systolic murmur on physical examination. An echocardiogram is performed, and she is found to have a bicuspid aortic valve.

In explaining the meaning of this finding to her, which is the most appropriate statement?

(Please select 1 option)

◉	An aortic valve replacement is eventually likely to be required ✓ Correct
○	Other family members are likely to have the same condition
○	She should be treated with a cholesterol-lowering agent
○	The problem has resulted from past injection drug usage
○	This is one manifestation of an underlying autoimmune disease process

Bicuspid aortic valve (BAV) is perhaps the most common form of congenital heart disease in adults (1-2% of population).

Bicuspid valves have a propensity to wear out and calcify with ageing. Bicuspid aortic valve tends to be sporadic although there is a reported familial incidence of approximately 9%.

From a review of several sources in the literature, the Aeromedical Consultation Service (ACS) at Brooks AFB calculated a 1.2% per year incidence of aortic valve surgery in individuals with BAV, although the vast majority occur in the fifth and sixth decades of life.

Triglycerides	1.3 mmol/l	(0.5-1.7)
LDL-cholesterol	1.9 mmol/l	(<2.6)
HDL-cholesterol	0.7 mmol/l	(0.7-1.7)

Which of the following changes of treatment would be expected to raise his HDL cholesterol level by the greatest amount?

(Please select 1 option)

- Add cholestyramine
- Add ezetimibe ✕ Incorrect answer selected
- Add fenofibrate
- Add nicotinic acid ← This is the correct answer
- Switch atorvastatin to rosuvastatin

Nicotinic acid is highly effective at raising high density lipoprotein (HDL) cholesterol but it is often poorly tolerated. Sustained release versions are less likely to induce flushing.

"Nicotinic acid is the most powerful HDL-cholesterol raising agent currently available, and a combination of this agent with a statin facilitates simultaneous control of both HDL-cholesterol and LDL-cholesterol." European Heart Journal Supplements, 2006, Volume 8, Suppl F, pages F23-F29

Work Smart Session - MRCP Part 1

Question: 70 of 100

A 40-year-old man received an orthotopic cardiac transplant seven years ago to treat a dilated cardiomyopathy. Since that time he has been healthy, with no episodes of rejection or infection. Over the next year, however, he develops fatigue with exercise. He has worsening pedal oedema and orthopnoea.

On physical examination, his vital signs are temperature 36.3°C, pulse 78, respiratory rate 16, and BP 130/70 mm Hg. There are no murmurs, rubs, or gallops audible. Bibasilar crackles in the lungs are audible.

Which of the following conditions is most likely to account for these findings?

(Please select 1 option)

○	Angiosarcoma
◉	Coronary arteriopathy
○	Mitral valvular stenosis
○	Myocarditis
○	Pulmonary hypertension

Submit answer | Skip question | Tag Question | Remove question

Question: 70 of 100

A 40-year-old man received an orthotopic cardiac transplant seven years ago to treat a dilated cardiomyopathy. Since that time he has been healthy, with no episodes of rejection or infection. Over the next year, however, he develops fatigue with exercise. He has worsening pedal oedema and orthopnoea.

On physical examination, his vital signs are temperature 36.3°C, pulse 78, respiratory rate 16, and BP 130/70 mm Hg. There are no murmurs, rubs, or gallops audible. Bibasilar crackles in the lungs are audible.

Which of the following conditions is most likely to account for these findings?

(Please select 1 option)

○	Angiosarcoma
◉	Coronary arteriopathy ✓ Correct
○	Mitral valvular stenosis
○	Myocarditis
○	Pulmonary hypertension

By five years following cardiac transplantation, nearly all patients have some degree of small coronary vascular narrowing.

Myocarditis is unlikely to be present in the absence of rejection or infection.

Question: 71 of 100

A 66-year-old man has developed chronic renal failure with a serum urea of 60 mmol/l (2.5-7.5) and creatinine of 650 mol/l (60-110).

Auscultation of the chest reveals a friction rub over the cardiac apex.

Which of the following types of pericarditis is he likely to have?

(Please select 1 option)

- Constrictive
- Fibrinous
- Haemorrhagic
- Purulent
- Serous

Submit answer | Skip question | Tag Question | Remove question

Question: 71 of 100

A 66-year-old man has developed chronic renal failure with a serum urea of 60 mmol/l (2.5-7.5) and creatinine of 650 mol/l (60-110).

Auscultation of the chest reveals a friction rub over the cardiac apex.

Which of the following types of pericarditis is he likely to have?

(Please select 1 option)

○	Constrictive
◉	Fibrinous ✓ Correct
○	Haemorrhagic
○	Purulent
○	Serous

The uraemia leads to exudation of fibrin onto the epicardial and pericardial surfaces.

Haemorrhagic pericarditis is more typical of tuberculosis or metastatic tumour.

Serous pericarditis is more typical of collagen vascular diseases.

Question: 72 of 100

A new antihypertensive drug needs to be investigated to establish its relative potency.

Which of the following techniques is most appropriate for this purpose?

(Please select 1 option)

○	Bioassay ← This is the correct answer
○	Case-control study
◉	Double-blind, randomised, placebo controlled study ✕ Incorrect answer selected
○	Postmarketing surveillance
○	Sequential trial

Biological assays are designed to measure the relative potency of different preparations.

Blood pressure is highly variable and is subject to variability because of the patient's level of anxiety and the method used by the observer to measure it.

In a test of **efficacy** of an antihypertensive drug, a double-blind, randomised design would be favourable.

A sequential trial (a trial in which the data are analysed after each participant's results become available and the trial continues until a clear benefit is seen in one of the comparison groups) could also be used to assess efficacy, but there would have to be a large expected difference from placebo.

Which one of the following statements is true about the Austin Flint murmur?

(Please select 1 option)

◉	It can be distinguished from the murmur of mitral stenosis by absence of presystolic accentuation ✕ Incorrect answer selected
○	It does not occur in aortic incompetence secondary to an aortitis
○	It is an early sign of aortic regurgitation (AR)
○	It is associated with a loud first heart sound.
○	It is a low frequency mid/late diastolic murmur ← This is the correct answer

The Austin Flint murmur is a low frequency mid/late diastolic murmur which may show pre-systolic accentuation and is virtually indistinguishable from that of mitral stenosis.

It is due to partial closure of the anterior leaflet of the mitral valve by the regurgitant jet.

There is no correlation between the presence of murmur and severity of AR, or aetiology.

The first heart sound is normal but in severe cases it may be absent.

Work Smart Session - MRCP Part 1

Question: 74 of 100

A 51-year-old businessman complains of dyspnoea on exertion. He recently returned from a business trip to the USA.

He has distant heart sounds on auscultation of the chest. A chest radiograph reveals that there is a thin rim of calcification surrounding the cardiac outline.

Which of the following conditions is most likely responsible for these findings?

(Please select 1 option)

- ○ Group B coxsackie virus
- ○ Metastatic carcinoma
- ○ Sarcoidosis
- ○ Tuberculosis
- ○ Uraemia

He has distant heart sounds on auscultation of the chest. A chest radiograph reveals that there is a thin rim of calcification surrounding the cardiac outline.

Which of the following conditions is most likely responsible for these findings?

(Please select 1 option)

○	Group B coxsackie virus
○	Metastatic carcinoma
○	Sarcoidosis
◉	Tuberculosis ✓ Correct
○	Uraemia

The most likely diagnosis is a constrictive pericarditis.

The most probable cause for this is prior tuberculous (TB) infection which may have occurred many years previously. Acute TB would usually cause a constrictive pericarditis secondary to a pericardial effusion, but is not normally associated with calcification.

Uraemia can cause a constrictive pericarditis, as can a pericardial malignancy and coxsackie virus (secondary to a pericarditis), but calcification would be unusual.

Sarcoid can cause both pericardial as well as restrictive cardiomyopathy but calcification would be unusual.

○	10
○	13 ← This is the correct answer
◉	15 ✕ Incorrect answer selected
○	20
○	23
○	12

This is a question concerning number needed to treat (NNT). The calculation involves a little arithmetic.

The absolute risk of MI in the group is a pretty high 10%, that is, of 1000 patients on placebo 100 will have MI over five years.

The relative risk reduction is stated as 0.8, that is, 80%.

Therefore, if you treat 1000 patients for five years with the cholesterol lowering agent you will get only 20 MIs.

Thus, for 1000 patients treated you will get 80 fewer MIs.

Thus number needed to treat to get one fewer MI is 1000/80 = 12.5.

Or, if you are any good at remembering formulae you can remember the following:

1. Relative risk reduction (RRR) = Absolute risk reduction (ARR) / Control event rate (CER)

2. Numbers needed to treat (NNT) = 1 / Absolute risk reduction (ARR)

You can then just insert the figures into these formulae.

The control (or placebo) event rate (CER) is 10% or 0.10. The relative risk reduction is 0.80.

Inserting these figures into the above formulae.... RRR = ARR / CER 0.80 = ARR / 0.10 ARR = 0.80 * 0.10 = 0.08. Then the NNT can be calculated by NNT = 1 / ARR = 1 / 0.08 = 12.5.

The absolute risk of MI in the group is a pretty high 10%, that is, of 1000 patients on placebo 100 will have MI over five years.

The relative risk reduction is stated as 0.8, that is, 80%.

Therefore, if you treat 1000 patients for five years with the cholesterol lowering agent you will get only 20 MIs.

Thus, for 1000 patients treated you will get 80 fewer MIs.

Thus number needed to treat to get one fewer MI is 1000/80 = 12.5.

Or, if you are any good at remembering formulae you can remember the following:

1. Relative risk reduction (RRR) = Absolute risk reduction (ARR) / Control event rate (CER)

2. Numbers needed to treat (NNT) = 1 / Absolute risk reduction (ARR)

You can then just insert the figures into these formulae.

The control (or placebo) event rate (CER) is 10% or 0.10. The relative risk reduction is 0.80.

Inserting these figures into the above formulae…. RRR = ARR / CER 0.80 = ARR / 0.10 ARR = 0.80 * 0.10 = 0.08. Then the NNT can be calculated by NNT = 1 / ARR = 1 / 0.08 = 12.5.

However, if algebra is not your thing you could try working with real numbers.

Imagine a group of 100 patients (it makes the maths easier). In the control (or placebo group) 10% (or 10 patients) suffered an MI. The relative risk reduction is 0.8 or 80%.

Therefore, in the treatment group, there would be a reduction in events by 80% (of 10 patients) = 8 patients. The number of patients suffering an MI in the treatment would therefore be 10 - 8 = 2 patients.

It can therefore be said that treating 100 patients with the new drug would result in eight fewer MIs.

The number needed to treat to prevent one MI would be 100/8 = 12.5 patients.

Question: 76 of 100

A 55-year-old man with type 2 diabetes mellitus and ischaemic heart disease has been researching the internet!

He asks your opinion on laser transmyocardial revascularisation.

Which of the following statements about this technique is true?

(Please select 1 option)

○	Avoids the need for major surgery
◉	Damages the endocardium ✓ Correct
○	Involves destruction of coronary stenoses
○	Is of particular use in severe proximal coronary artery disease
○	Stimulates collateral vessel formation

Open chest surgery is undertaken, during which laser holes are punched from the epicardial surface into areas of suspected ischaemic or hibernating ventricular muscle. The process is not fully understood.

The epicardial end of the hole heals up leaving artificial channels communicating with the ventricular chamber and effectively forming new coronary vessels.

Laser transmyocardial revascularisation has potential in distal disease such as in diabetes.

Angioplasty and coronary artery bypass graft (CABG) are useful in proximal disease.

Question: 78 of 100

Which of the following compounds has a vasodilating effect?

(Please select 1 option)

○	Antidiuretic hormone (ADH)
◉	Calcitonin gene related peptide ✓ Correct
○	Endothelin
○	Renin
○	Somatostatin

ADH acts on the vasopressor receptors to cause vasoconstriction.

Endothelin is also a vasoconstrictor as is renin.

Somatostatin is also recognised to produce vasoconstriction of the splanchnic system.

Work Smart Session - MRCP Part 1

Question: 79 of 100

A 14-year-old boy presents with fever.

Which of the following might contribute to a diagnosis of rheumatic fever?

(Please select 1 option)

○	A CRP of 10
○	A prolonged PR interval on ECG
○	Finding target lesions on the hands
○	Finding tender nodules in the fingertips
○	Positive Romberg's sign

Submit answer | Skip question | Tag Question | Remove question

- Help

○	A CRP of 10
◉	A prolonged PR interval on ECG ✓ Correct
○	Finding target lesions on the hands
○	Finding tender nodules in the fingertips
○	Positive Romberg's sign

The modified Jones criteria include:

- Finding of preceding streptococcal infection (recent scarlet fever, raised ASOT or other streptococcal antibodies)
- Positive throat swab for Group A *Strep*.

Plus:

(a) Major Criteria:

- Carditis
- Polyarthritis
- Chorea
- Subcutaneous nodules
- Erythema marginatum.

(b) Minor Criteria:

- Fever
- Arthralgia
- Previous history of rheumatic fever

- Erythema marginatum.

(b) Minor Criteria:

- Fever
- Arthralgia
- Previous history of rheumatic fever
- Elevated acute phase reactions
- Prolonged PR interval.

Erythema marginatum involves red circular lesions which gradually enlarge with central clearing.

Sydenham's chorea consists of choreoathetoid movements with increased clumsiness, for example, deteriorating handwriting. This is often associated with emotional lability.

Target lesions suggest erythema multiforme.

A C-reactive protein (CRP) of 10 is not elevated much beyond the normal range.

Erythema marginatum initially manifests as non-specific pink macules seen over the trunk, with later blanching in the middle of the lesions and sometimes fusing of the borders resulting in a serpiginous (serpent-like) looking lesion. The rash is worsened with heat, but is characteristically evanescent. It does not itch, and can be mistaken for the rash of Lyme disease.

Sub-cutaneous nodules are pea-sized, firm and non-tender. There is no associated inflammation and they are characteristically seen on the extensor surfaces of joints such as knees and elbows and also over the spine.

Which of the following management options would be most helpful in this situation?

(Please select 1 option)

○	CT brain scan
◉	Diazepam ✓ Correct
○	Haloperidol
○	Psychiatric referral
○	Thiamine

This man is withdrawing from alcohol and this is associated with anxiety and tachycardia which is the last thing that someone who has just had a myocardial infarction (MI) should suffer from. Also there is a risk of seizure.

Benzodiazepines are the first line of treatment for withdrawal.

Thiamine is also indicated in chronic alcoholism but is not as immediately important as diazepam.

A psychiatric referral may be necessary if his symptoms prove difficult to control but usually the psychiatry team would not be keen to intervene in what is really a medical emergency; they often advise on other strategies for sedation however.

This is unlikely to be an intracerebral bleed from thrombolysis on the third day but a computerised tomography (CT) scan may be indicated if there are focal neurological signs.

Haloperidol is best avoided because of the risk of causing hypotension.

Work Smart Session - MRCP Part 1

Question: 80 of 100

A 14-year-old boy presents with hypertension.

Which of the following statements concerning hypertension in the young is true?

(Please select 1 option)

○	Abnormalities are frequently seen on DMSA scan
○	Aortic coarctation is the commonest secondary cause
○	Headache is the usual presenting feature
○	It is defined as systolic blood pressure above the 99th centile for age
○	Sodium nitroprusside is useful for the long-term treatment of severe cases

Submit answer | Skip question | Tag Question | Remove question

A 14-year-old boy presents with hypertension.

Which of the following statements concerning hypertension in the young is true?

(Please select 1 option)

◉	Abnormalities are frequently seen on DMSA scan ✓ Correct
○	Aortic coarctation is the commonest secondary cause
○	Headache is the usual presenting feature
○	It is defined as systolic blood pressure above the 99th centile for age
○	Sodium nitroprusside is useful for the long-term treatment of severe cases

Sodium nitroprusside is useful only in the short term, as cyanide levels accumulate with time.

Hypertension is usually diagnosed incidentally, and is defined as systolic blood pressure greater than the 95th centile for age.

Secondary causes are usually due to renal abnormalities, with reflux-associated scarring being the commonest renal disease. This will cause abnormalities on dimercaptosuccinic acid (DMSA) scan.

Coarctation of the aorta is the commonest non-renal cause, with pheochromocytoma/neuroblastoma, congenital adrenal hyperplasia, Cushing's syndrome and steroid therapy being rarer causes.

Work Smart Session - MRCP Part 1

Question: 82 of 100

Which of the following concerning the use of intravenous bicarbonate in cardiorespiratory arrest is correct?

(Please select 1 option)

○	Exacerbates intracellular acidosis ← This is the correct answer
○	Has a positive inotropic effect on ischaemic myocardium
○	Improves oxygen release to the tissues
◉	Increases cerebral blood flow ✕ Incorrect answer selected
○	Reduces pre-existent hyperkalaemia

Bicarbonate therapy can increase extracellular pH only if the carbon dioxide (CO_2) produced can be removed by adequate ventilation.

Indeed, if hypercapnia occurs then as CO_2 crosses cell membranes easily, intracellular pH may decrease even further with further deterioration of cellular function.

Bicarbonate has a negative inotropic effect, reducing cerebral blood flow; it shifts the oxygen dissociation curve to the left, inhibiting oxygen release to tissues.

Question: 83 of 100

On auscultation of the heart of a 30-year-old female a loud first heart sound is heard.

Which of the following may be responsible for this auscultatory feature?

(Please select 1 option)

- A long preceding diastolic interval
- Atrial premature beat
- Increased pulmonary arterial pressure
- Increased systemic arterial pressure
- Rupture of a papillary muscle

Submit answer | Skip question | Tag Question | Remove question

Time taken: 2 hrs 11 mins 7 secs

Work Smart Session - MRCP Part 1

Question: 83 of 100

On auscultation of the heart of a 30-year-old female a loud first heart sound is heard.

Which of the following may be responsible for this auscultatory feature?

(Please select 1 option)

○	A long preceding diastolic interval
◉	Atrial premature beat ✓ Correct
○	Increased pulmonary arterial pressure
○	Increased systemic arterial pressure
○	Rupture of a papillary muscle

A loud first heart sound is due to abrupt closure of the mitral valve against a high left atrial pressure and may occur with shortened diastole, mitral stenosis or left-right shunts.

It can also be heard with atrial premature beats.

Mitral regurgitation (MR) occurs with papillary muscle rupture and thereby the first heart sound is soft. A2 and P2 are loud in systemic hypertension (HT) and pulmonary hypertension respectively.

Work Smart Session - MRCP Part 1

Question: 84 of 100

A 26-year-old man is noted to have cyanosis of the lower limbs and clubbing of the toes but not the fingers.

Which of the following statements is true?

(Please select 1 option)

○	He has coarctation of the aorta
○	He has Eisenmenger's syndrome
○	He has had a Blalock shunt operation
○	He is likely to have a loud continuous 'machinery' murmur below the left clavicle
○	He is likely to need urgent surgery

Submit answer | Skip question | Remove Tag | Remove question

Which of the following statements is true?

(Please select 1 option)

○	He has coarctation of the aorta
◉	He has Eisenmenger's syndrome ✓ Correct
○	He has had a Blalock shunt operation
○	He is likely to have a loud continuous 'machinery' murmur below the left clavicle
○	He is likely to need urgent surgery

This is the differential cyanosis of a reversed patent ductus arteriosus (PDA). There is a right-left shunt from the pulmonary artery to the aorta just distal to the left subclavian artery.

Coarctation causes radiofemoral delay. It may be associated with PDA but there is no suggestion in this patient.

Continuous machinery murmur is the classic murmur of PDA but when the shunt reverses (as in patients with a large PDA and/or pulmonary disease) the murmur becomes softer and shorter.

When Eisenmenger's syndrome has developed surgery is associated with a very high mortality.

A Blalock shunt (anastomosis of subclavian artery to pulmonary artery) used to be performed for Fallot's tetralogy and leads to a weak left radial pulse.

Question: 85 of 100

Which of the following statements concerning the treatment of acute myocardial infarction (MI) is correct?

(Please select 1 option)

○	A pansystolic murmur developing within the first 24 hours does not require further investigation
○	Dipyridamole therapy reduces reinfarction within the first year
○	Heparin is beneficial if given with streptokinase
○	Prophylactic lidocaine given in the first 48 hours is effective in preventing ventricular fibrillation
◉	Treatment with a dihydropyridine calcium antagonist is associated with increased cardiovascular mortality ✓ Correct

GISSI II revealed no survival advantage of heparin plus streptokinase in acute MI compared with streptokinase alone.

ISIS II revealed that dihydropyridine calcium antagonists were associated with increased cardiovascular risk after MI.

Dipyridamole does not reduce risk.

A newly discovered pansystolic murmur may signify acquired mitral regurgitation (MR) or ventricular septal defect (VSD).

Question: 86 of 100

An 80-year-old man presents with an inferior MI and receives thrombolysis.

Four hours following initial presentation he becomes acutely breathless.

His ECG demonstrates sinus tachycardia (rate 108 bpm) with T wave inversion inferiorly. His ST segments are normal.

On examination his JVP is elevated at 5 cm. Chest was clear to auscultation.

Following the administration of 80 mg furosemide he deteriorates.

His BP is now 80/60 mmHg and his urine output over the last two hours is 5 mls.

What is the best investigative measure?

(Please select 1 option)

○	Arterial blood gases
○	Central venous pressure (CVP) monitoring
○	Chest x ray
○	Echocardiography
○	Pulmonary capillary wedge pressure monitoring

Submit answer | Skip question | Tag Question | Remove question

His BP is now 80/60 mmHg and his urine output over the last two hours is 5 mls.

What is the best investigative measure?

(Please select 1 option)

○	Arterial blood gases
○	Central venous pressure (CVP) monitoring
○	Chest x ray
◉	Echocardiography ✕ Incorrect answer selected
○	Pulmonary capillary wedge pressure monitoring ← This is the correct answer

The scenario is that of a right ventricular myocardial infarction (MI).

The treatment in this situation is to give fluid in order to increase left ventricular end-diastolic pressure (LVEDP).

Furosemide will only worsen the situation.

The best way to determine if adequate fluid is being given is using a Swan-Ganz catheter to monitor pulmonary capillary wedge pressure ([PCWP], a surrogate for left atrial pressure).

CVP is increased in LV failure due to the infarct, so monitoring it would not help to guide treatment.

Echocardiography would show a small volume LV with a dilated right ventricle (RV).

Work Smart Session - MRCP Part 1

Question: 87 of 100

A 21-year-old man with hypertrophic cardiomyopathy presents in clinic with dizzy spells but has not had any syncopal episodes.

Which of the following, if present, would indicate an increased risk of sudden cardiac death?

(Please select 1 option)

○	Asymmetric septal hypertrophy with maximum wall thickness of 2.1 cm
○	Blood pressure drop of 20 mmHg during peak exercise tolerance testing
○	Left ventricular outflow tract gradient of 80 mmHg
○	Systolic anterior movement of the mitral valve on echocardiography
○	Worsening exertional angina

Submit answer | Skip question | Tag Question | Remove question

(Please select 1 option)

○	Asymmetric septal hypertrophy with maximum wall thickness of 2.1 cm
◉	Blood pressure drop of 20 mmHg during peak exercise tolerance testing ✓ Correct
○	Left ventricular outflow tract gradient of 80 mmHg
○	Systolic anterior movement of the mitral valve on echocardiography
○	Worsening exertional angina

Patients with hypertrophic cardiomyopathy (HCM) are at increased risk of sudden cardiac death due to ventricular fibrillation/tachycardia (VF/VT).

The five poor prognostic markers which are predictive of sudden cardiac death are:

1. Syncope
2. Family history of HCM and sudden cardiac death
3. Maximum left ventricular wall thickness greater than 3 cm
4. Blood pressure drop during peak exercise on stress testing
5. Documented runs of non-sustained VT on 24 hour tape.

Left ventricular outflow tract (LVOT) obstruction causes symptoms and can lead to deterioration of LV function but does not predict sudden cardiac death.

Asymmetric septal hypertrophy is a feature of HCM; in order to assess the risk for sudden cardiac death a detailed echocardiogram with measurements of the maximum left ventricular wall thickness is required.

Systolic anterior movement of the mitral valve is often seen on echocardiogram and is thought to be the mechanism behind the left ventricular outflow tract obstruction.

Work Smart Session - MRCP Part 1

Question: 88 of 100

A 75-year-old man with a history of anterior MI is taking amiodarone 400 mg/day for history of VT. He has a prolonged QT interval on his ECG.

What is the most appropriate management?

(Please select 1 option)

○	Admit to hospital for monitoring
◉	Atenolol ✕ Incorrect answer selected
○	Change amiodarone to flecainide
○	Continue with amiodarone
○	Discontinue amiodarone immediately ← This is the correct answer

In iatrogenic long QT, which is what this is likely to be, it is safer to stop the offending drug rather than add further drugs on board (for example, beta-blockers even though atenolol is used for long QT).

Flecainide is clearly contraindicated in this situation (CAST study).

Question: 89 of 100

A 60-year-old man had a myocardial infarction (MI) six weeks ago.

He is taking aspirin 75 mg/day and metoprolol 50 mg 2/day.

During a routine follow-up exercise test he has a 20 beat run of non-sustained VT. He achieved stage 4 of the Bruce protocol and 92% of his target heart rate. The non-sustained VT occurred halfway through stage 2. ST segments were normal during the study.

What is the definitive investigation?

(Please select 1 option)

○	Coronary angiography
○	Echocardiogram
○	Electrophysiological study (EPS)
○	Thallium exercise scan
○	24 hour Holter monitor

Submit answer | Skip question | Tag Question | Remove question

○	Coronary angiography
○	Echocardiogram
◉	Electrophysiological study (EPS) ✓ Correct
○	Thallium exercise scan
○	24 hour Holter monitor

Post MI ventricular tachycardia (VT) is most commonly due to scar tissue. It may also be related to ischaemia, but no signs of ischaemia were induced.

The definitive investigation would be EPS due to the fact that if this were scar-related VT the site could be localised and even possibly ablated. If not, then an implantable cardio-defibrillator (ICD) implantation may be warranted on MADIT criteria, if left ventricular (LV) dysfunction exists.

Angiography plus thallium may inform us of significant coronary artery disease (CAD) but not offer us a solution to the problem.

An echocardiogram would not be of much use apart from assessing LV function, although in this patient one might assume that LV function is pretty good achieving stage 4 of Bruce protocol, thus an echocardiogram, although required, would not be the definitive test and would be down on the selection list.

There is no need for Holter as the VT has already been recorded.

The reference for MADIT is AmJCardiol 1997;79 (suppl 6A):16-7. It was stopped early in 1996 by the steering committee due to extremely positive results in the ICD group. As a consequence it was only published in abstract form. However, MADIT-2 published in the NEJM (Ref: N Engl J Med 2002; 346:877-883, Mar 21, 2002) showed a 5.6% 20 month absolute survival benefit in patients with LV dysfunction (EF<30%), post MI, treated prophylactically with an ICD.

Work Smart Session - MRCP Part 1

Time taken: 12 mins 21 secs

Question: 8 of 100

A 60-year-old man presented with a rash over his forearms, shins and face when he visited cardiology clinic in the summer.

Which of the following medications is the most likely to be associated with this photosensitive rash?

(Please select 1 option)

○	Atenolol
◉	Bendroflumethiazide ✓ Correct
○	Clopidogrel
○	Digoxin
○	Ezetimibe

Photosensitivity is a common adverse effect and the cardiology drugs affected include amiodarone and thiazide diuretics.

Angiotensin-converting enzyme (ACE) inhibitors and angiotensin 2 receptor blockers (A2RBs) commonly cause rashes some of which appear to be photosensitive.

Work Smart Session - MRCP Part 1

Question: 90 of 100

A 75-year-old lady presents with sudden breathlessness and palpitations.

On examination, she was observed to have an irregular heart beat with rate of 140 bpm, BP 98/64 mmHg and normal heart sounds. On auscultation of the chest, fine basal crepitations are heard.

An ECG confirms atrial fibrillation (AF) and an old inferior myocardial infarction. She is anticoagulated with heparin and given diuretics. Her heart rate remains rapid.

What is the most appropriate management of the lady's AF?

(Please select 1 option)

- DCCV
- IV amiodarone
- IV beta-blocker
- IV digoxin
- Oral quinidine therapy

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

What is the most appropriate management of the lady's AF?

(Please select 1 option)

◉	DCCV ✓ Correct
○	IV amiodarone
○	IV beta-blocker
○	IV digoxin
○	Oral quinidine therapy

The key to this question is that the patient has clinical signs of pulmonary oedema with fast AF and hypotension.

In this age group AF is poorly tolerated and often leads to pulmonary oedema even in the presence of a relatively normal left ventricle (LV).

NICE have published guidance on the treatment of AF.

The primary aim here should be rate control which is best achieved with direct current cardioversion (DCCV) in this situation.

Digoxin even when used intravenously is suggested to have too slow an onset of action to merit its use.

Beta-blockers can also be used but due to the fact that they are negatively inotropic may complicate the acute pulmonary oedema.

Emergency DCCV is required as there is haemodynamic compromise (low BP).

Work Smart Session - MRCP Part 1

Question: 91 of 100

A 17-year-old girl was found collapsed and drowsy.

Her 12-lead ECG showed a sinus tachycardia of 120 beats per minute with a corrected QT interval of 500 ms (normal <470).

Which of the following drugs is the most likely cause of her presentation?

(Please select 1 option)

○	Amphetamine
○	Diphenhydramine
○	Glue sniffing
○	Methadone
○	Methanol

Submit answer | Skip question | Tag Question | Remove question

Question: 91 of 100

A 17-year-old girl was found collapsed and drowsy.

Her 12-lead ECG showed a sinus tachycardia of 120 beats per minute with a corrected QT interval of 500 ms (normal <470).

Which of the following drugs is the most likely cause of her presentation?

(Please select 1 option)

○	Amphetamine
○	Diphenhydramine ← This is the correct answer
○	Glue sniffing
◉	Methadone ✕ Incorrect answer selected
○	Methanol

You are given here the option of choosing between two drugs that can possibly cause prolongation of QT - diphenhydramine and methadone.

However, bearing in mind that she has collapsed and is drowsy with a tachycardia, the most likely option is diphenhydramine as the tachycardia is more typical.

Many drugs can cause a prolonged QT interval. More here.

Work Smart Session - MRCP Part 1

Question: 93 of 100

A 65-year-old was advised to start oral digoxin at a dose of 250 µg daily. His physician explained that the full effect of this treatment would not be apparent for at least a week.

Which one of the following pharmacokinetic variables did the physician use to give this explanation?

(Please select 1 option)

◉	Bioavailablity ✗ Incorrect answer selected
○	Half life ← This is the correct answer
○	Plasma protein binding
○	Renal clearance
○	Volume of distribution

Digoxin follows first order kinetics and has a half life of 1.6 days in a patient with normal renal function.

65% of the drug absorbed remains in the system after one day.

Subsequent doses gradually accumulate until a steady state is achieved after four to five days.

Question: 94 of 100

A 55-year-old man presents with gynaecomastia. He is receiving treatment for heart failure and gastro-oesophageal reflux.

Which of the following drug he takes is most likely to be responsible for his gynaecomastia?

(Please select 1 option)

- Amitryptiline
- Carvedilol
- Furosemide
- Omeprazole
- Ramipril

Submit answer | Skip question | Tag Question | Remove question

A 55-year-old man presents with gynaecomastia. He is receiving treatment for heart failure and gastro-oesophageal reflux.

Which of the following drug he takes is most likely to be responsible for his gynaecomastia?

(Please select 1 option)

○	Amitryptiline
○	Carvedilol
○	Furosemide
◉	Omeprazole ✓ Correct
○	Ramipril

Like cimetidine, omeprazole is associated with gynaecomastia.

The other agents are not associated.

Other causes of gynaecomastia include

- spironolactone
- amiloride
- to a lesser extent eplerenone
- digoxin
- luteinising hormone-releasing hormone (LHRH) analogues
- finasteride.

Work Smart Session - MRCP Part 1

Question: 95 of 100

On discovering an unconscious patient in a pre-hospital environment basic life support needs to be considered.

Which of the following statements is correct?

(Please select 1 option)

- Cross infection with hepatitis B may occur during CPR
- On confirming an arrest, a ratio of 30 compressions to 2 ventilations should be adopted at all times
- On confirming an arrest, one minute of CPR should be performed before leaving the patient and getting help
- Rapid assessment of the airway and breathing is our primary objective
- Two effective rescue breaths should be given once apnoea is confirmed

Submit answer | Skip question | Tag Question | Remove question

	On confirming an arrest, one minute of CPR should be performed before leaving the patient and getting help
	Rapid assessment of the airway and breathing is our primary objective
	Two effective rescue breaths should be given once apnoea is confirmed

Assessing the environment to see if it is safe to approach is the first priority when considering providing aid to an unconscious patient. You do not want to become a casualty yourself.

Cardiopulmonary resuscitation (CPR) related infections are extremely rare, although tuberculosis, human immunodeficiency virus (HIV) and *Neisseria meningitidis* have all been recorded.

Most of the 15 cases were due to bacterial agents and the three HIV infections were from major cutaneous wound contamination.

No case reports of hepatitis B have been recorded (Ann Int Med 1998;129(10):813-828).

Once it has been confirmed that the patient is not breathing you must get help or alert the emergency services, even if this means leaving the patient (this is especially important in a pre-hospital environment).

However, if the patient is an infant or child, a victim of trauma, a near drowning or if drug or alcohol intoxication is likely, then one minute of CPR should be performed before going for help.

The new ALS guidelines (pdf) correct ratio of compressions to ventilations is 30:2 regardless of the number of rescuers present.

EN 11:34 PM 3/1/2011

Question: 99 of 100

Which of the following anti-arrhythmic drugs may be used in the treatment of long QT syndrome?

(Please select 1 option)

○	Amiodarone
◉	Atenolol ✓ Correct
○	Flecainide
○	Propafenone
○	Sotalol

Beta-blockers are the mainstay of treatment in long QT syndrome.

The most commonly used drugs are propranolol and nadolol, but metoprolol and atenolol are also used.

Implantable cardioverter-defibrillators are the most effective treatment in high risk cases.

The others drugs may produce a prolongation of the QT interval, exacerbating risk of polymorphic ventricular tachycardia (VT) and torsades de pointes.

Question: 9 of 100

Which of the following mechanisms best explains the action of fibrates?

(Please select 1 option)

○	Activation of PPAR-alpha ← This is the correct answer
◉	Bile acid sequestration ✕ Incorrect answer selected
○	Decreases hepatic cholesterol synthesis
○	Increases peroxisomal beta-oxidation of fatty acids
○	Inhibits cholesterol absorption

The effect of fibrates on the metabolism of triglyceride-rich lipoproteins is due to a peroxisome proliferator activating receptor (PPAR)-alpha-dependent stimulation of lipoprotein lipase and of apolipoprotein (apo)A-V and to an inhibition of apoC-III expression, whereas the increase in plasma high density lipoprotein (HDL)-cholesterol depends partly on an overexpression of apoA-I and apoA-II. Drugs Today (Barc). 2006 Jan;42(1):39-64

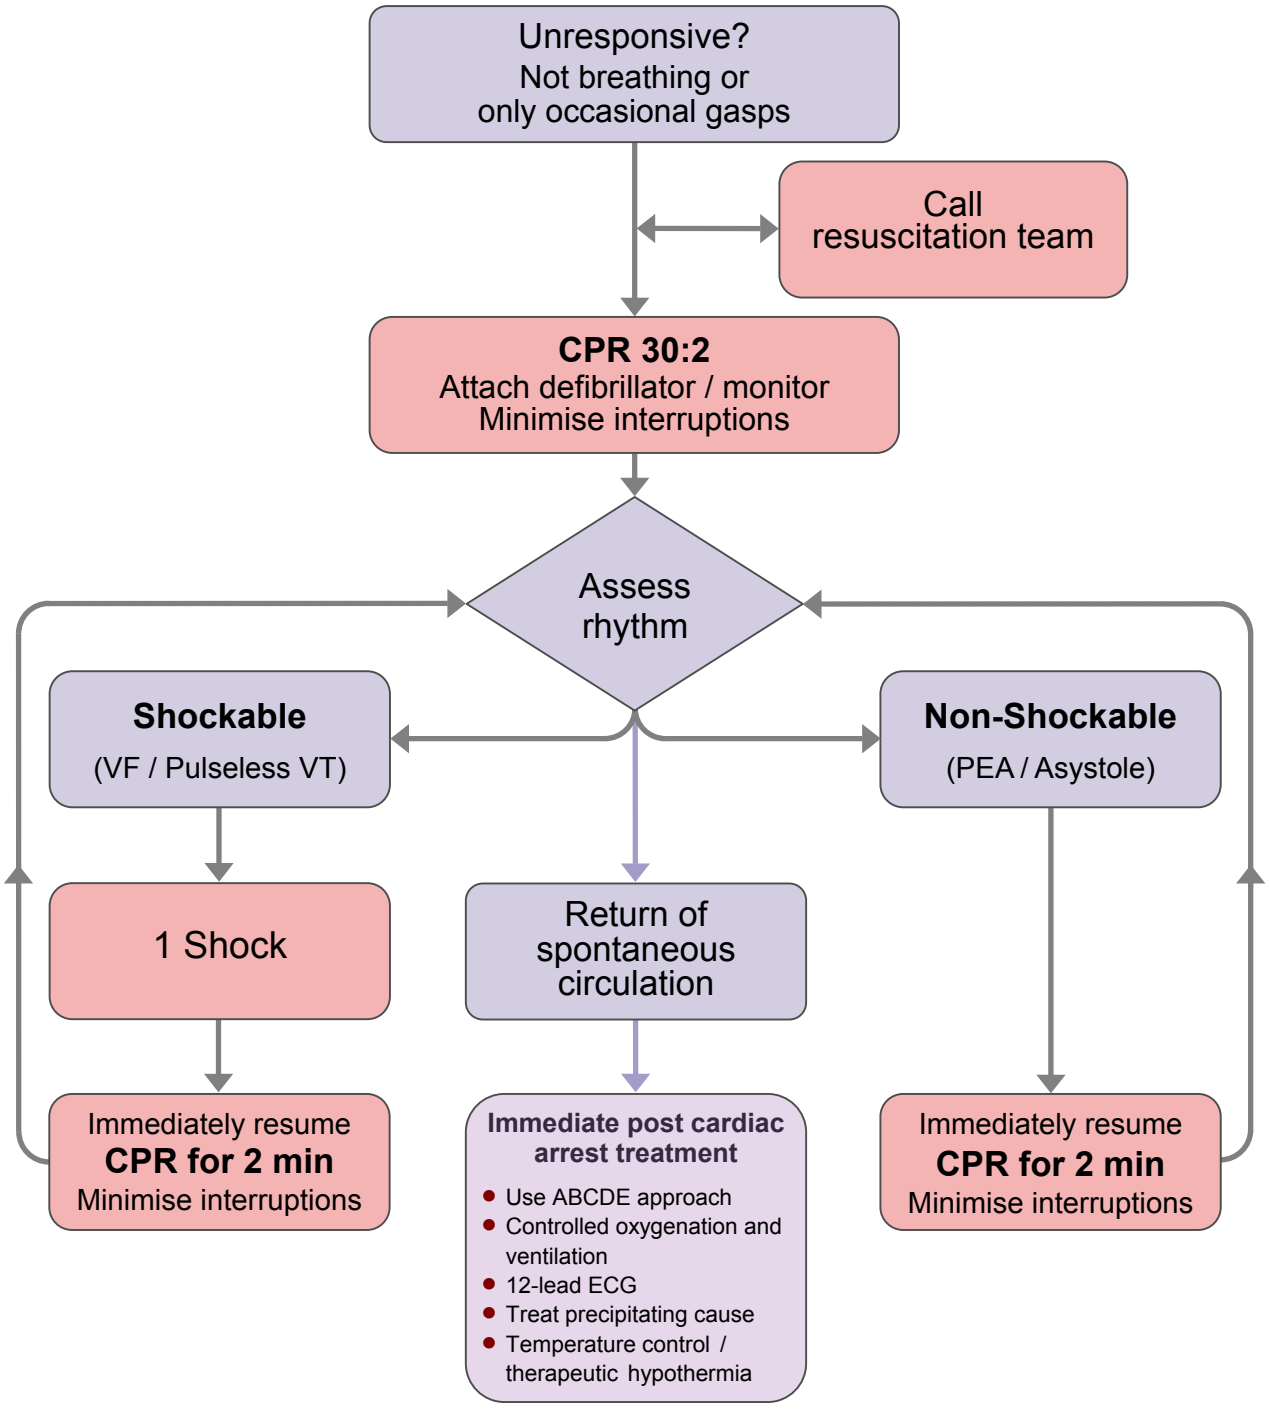
2010 Resuscitation Guidelines

Resuscitation Council (UK)

Adult Advanced Life Support



During CPR

- Ensure high-quality CPR: rate, depth, recoil
- Plan actions before interrupting CPR
- Give oxygen
- Consider advanced airway and capnography
- Continuous chest compressions when advanced airway in place
- Vascular access (intravenous, intraosseous)
- Give adrenaline every 3-5 min
- Correct reversible causes

Reversible Causes

- Hypoxia
- Hypovolaemia
- Hypo- / hyperkalaemia / metabolic
- Hypothermia
- Thrombosis - coronary or pulmonary
- Tamponade - cardiac
- Toxins
- Tension pneumothorax

Question: 100 of 100

Which molecule is produced in the nucleus, matures in the cytoplasm, binds to the ribosome and initiates protein synthesis?

(Please select 1 option)

◉	Messenger RNA ✓ Correct
○	Ribosomal RNA
○	RNA nucleotide
○	RNA polymerase
○	Transfer RNA

Protein synthesis consists of two phases.

Transcription is where one strand of the deoxyribonucleic acid (DNA) double helix is used as a template by ribonucleic acid (RNA) polymerase to synthesise messenger RNA from RNA nucleotides.

The mRNA then migrates into the cytoplasm maturing, for example, by the splicing of non-coding sequences.

Translation occurs when the ribosome binds to mRNA at the start codon and transfer RNA brings amino acids into position along the mRNA template.

The ribosome moves from codon to codon along the mRNA producing a polypeptide sequence.

Question: 10 of 100

A 20-year-old woman was referred for investigation of iron deficiency anaemia. Her mother died aged 28 years from colonic carcinoma complicating Peutz-Jegher syndrome.

Which is the most likely mode of inheritance of Peutz-Jegher syndrome?

(Please select 1 option)

◉	Autosomal dominant ✓ Correct
○	Autosomal recessive
○	Mitochondrial
○	Polygenic
○	X linked dominant

Peutz-Jegher syndrome is a condition characterised by perioral pigmentation and numerous hamartomas of the bowel.

Originally it was assumed that these did not predispose to malignancy but studies now suggest the contrary.

The condition is autosomal dominant.

Work Smart Session - MRCP Part 1

Time taken: 16 mins 18 secs

Question: 11 of 100

A clinical trial assessing a new lipid lowering therapy for stroke allocates 1000 patients to active treatment and another 1000 patients to placebo.

Results demonstrate that the number needed to treat (NNT) is 20 for the prevention of the primary end-point.

Which of the following best describes the results?

(Please select 1 option)

- 20 patients in the treatment group were protected from stroke
- 20 extra patients in the placebo group had a stroke
- For 1000 patients treated with active therapy, there would be 20 fewer strokes
- For 1000 patients treated with active therapy, there would be 50 fewer strokes
- For every 1000 patients treated with active therapy there would be 100 fewer strokes

Work Smart Session - MRCP Part 1

Time taken: 30 mins 19 secs

Question: 11 of 100

A clinical trial assessing a new lipid lowering therapy for stroke allocates 1000 patients to active treatment and another 1000 patients to placebo.

Results demonstrate that the number needed to treat (NNT) is 20 for the prevention of the primary end-point.

Which of the following best describes the results?

(Please select 1 option)

○	20 patients in the treatment group were protected from stroke
○	20 extra patients in the placebo group had a stroke
◉	For 1000 patients treated with active therapy, there would be 20 fewer strokes ✕ Incorrect answer selected
○	For 1000 patients treated with active therapy, there would be 50 fewer strokes ← This is the correct answer
○	For every 1000 patients treated with active therapy there would be 100 fewer strokes

This prevention study for stroke reveals that 20 patients need to be treated to prevent one event.

Thus if you treat a 1000 patients then you will expect to have 50 fewer strokes.

Work Smart Session - MRCP Part 1

Time taken: 30 mins 19 secs

Question: 12 of 100

There is presently no known effective treatment for a chronic disease.

A new treatment is known to be effective in animal models and shows promise in short-term studies in patients. There are some theoretical concerns regarding possible hepato- and bone marrow toxicity although, thus far, no toxicity has been observed in studies.

What is the most appropriate next step in the drug's development?

(Please select 1 option)

- A case control study
- An open study
- A randomised double-blind placebo-controlled study
- A randomised single-blind placebo-controlled study
- No further studies should be done and drug development should be stopped

Submit answer | Skip question | Tag Question | Remove question

There is presently no known effective treatment for a chronic disease.

A new treatment is known to be effective in animal models and shows promise in short-term studies in patients. There are some theoretical concerns regarding possible hepato- and bone marrow toxicity although, thus far, no toxicity has been observed in studies.

What is the most appropriate next step in the drug's development?

(Please select 1 option)

◉	A case control study ✕ Incorrect answer selected
○	An open study
○	A randomised double-blind placebo-controlled study ← This is the correct answer
○	A randomised single-blind placebo-controlled study
○	No further studies should be done and drug development should be stopped

It appears that the drug has undergone animal testing and we can surmise that it has also been tested on normal volunteers (phase 1) as we are told that it has been tried in short-term studies of patients (phase 2).

After this testing process comes phase 3 studies - broad clinical trials designed to determine whether the drug is of clinical benefit in the disease state.

In particular you wish to know whether the drug is effective or not and you wish to know its safety.

A double-blind placebo-controlled study would be best placed to provide this information.

Work Smart Session - MRCP Part 1

Time taken: 32 mins 53 secs

Question: 13 of 100

In a trial of a new drug the following results were obtained:

	Improved	Not improved
Treatment group	44	16
Placebo group	36	26

Which of the following statements regarding the statistical analysis or interpretation of the trial is true?

(Please select 1 option)

- A Student *t*-test could be used
- Pearson's co-efficient of linear regression would be an appropriate significance test
- The data could be evaluated using the chi-squared test
- The numbers are too small to draw any conclusions
- The results so obviously show the benefit of treatment that statistical analysis is not required

	Improved	Not improved
Treatment group	44	16
Placebo group	36	26

Which of the following statements regarding the statistical analysis or interpretation of the trial is true?

(Please select 1 option)

- A Student *t*-test could be used
- Pearson's co-efficient of linear regression would be an appropriate significance test
- The data could be evaluated using the chi-squared test ✓ Correct
- The numbers are too small to draw any conclusions
- The results so obviously show the benefit of treatment that statistical analysis is not required

These data would be ideal for a chi-squared test. It is a 2 x 2 contingency table for which there is a special Chi-squared formula that gives a value that can be looked up in a table giving the p value.

The Student *t*-test cannot be used as we are comparing proportions not means.

Pearson's co-efficient cannot be calculated as there is no linear regression to plot.

Nothing is ever so obvious that no statistical analysis is needed, surely?

Work Smart Session - MRCP Part 1

Time taken: 35 mins 6 secs

Question: 14 of 100

Which of the following regarding the anatomy of the heart is true?

(Please select 1 option)

- The aortic valve is tricuspid
- The ascending aorta is entirely outside the pericardial sac
- The left atrial appendage is identified readily by transthoracic echocardiography
- The right atrium is posterior to the left atrium
- The right branch of the pulmonary artery lies anterior to the ascending aorta

Work Smart Session - MRCP Part 1

Time taken: 36 mins 18 secs

Question: 14 of 100

Which of the following regarding the anatomy of the heart is true?

(Please select 1 option)

- (●) The aortic valve is tricuspid ✓ Correct
- ( ) The ascending aorta is entirely outside the pericardial sac
- ( ) The left atrial appendage is identified readily by transthoracic echocardiography
- ( ) The right atrium is posterior to the left atrium
- ( ) The right branch of the pulmonary artery lies anterior to the ascending aorta

The right branch of the pulmonary artery lies posterior to the ascending aorta.

The ascending aorta lies completely within the pericardium as does the pulmonary trunk.

The left atrium is the most posterior chamber of the heart; the right atrium is just anterior and to the right of the left atrium.

The left atrial appendage is not readily seen on transthoracic echocardiography and requires transoesophageal echocardiography.

Work Smart Session - MRCP Part 1

Time taken: 36 mins 18 secs

Question: 15 of 100

Concerning neurofibromatosis type 1 (NF1), which one of the following statements is true?

(Please select 1 option)

- Bilateral acoustic neuromas are common
- Clinical severity in individuals is similar in a given family
- New mutations occur rarely
- Pigmented spots on the iris are a characteristic feature
- The diagnosis is likely if two café au lait patches are present

Work Smart Session - MRCP Part 1

Time taken: 38 mins 25 secs

Question: 15 of 100

Concerning neurofibromatosis type 1 (NF1), which one of the following statements is true?

(Please select 1 option)

○	Bilateral acoustic neuromas are common
○	Clinical severity in individuals is similar in a given family
○	New mutations occur rarely
◉	Pigmented spots on the iris are a characteristic feature ✓ Correct
○	The diagnosis is likely if two café au lait patches are present

Lisch nodules of the iris are present in more than 90% of patients.

Bilateral acoustic neuromas are a hallmark feature of neurofibromatosis type 2.

Expressivity of the gene is highly variable and members of the same family usually show wide differences in clinical symptoms.

NF1 is one of the most common autosomal dominant conditions. However almost half of all cases give no family history and are new mutations. The mutation rate is estimated to be 1:10,000 gametes.

The diagnosis is suggested by six or more café au lait macules (spots), each over 5 mm in diameter in prepubescent individuals and over 15 mm in post pubertal individuals.

Work Smart Session - MRCP Part 1

Time taken: 38 mins 25 secs

Question: 16 of 100

Which of the following statements is true about immunological reactions?

(Please select 1 option)

- Angio-neurotic oedema is the most severe form of type I reaction
- Deficiencies in the terminal components of complement increase the risk of meningococcal disease
- Graves' disease is caused by a type IV reaction
- Serum sickness is caused by a type II reaction
- Urticaria usually responds to cimetidine

Work Smart Session - MRCP Part 1

Time taken: 40 mins 47 secs

Question: 16 of 100

Which of the following statements is true about immunological reactions?

(Please select 1 option)

- Angio-neurotic oedema is the most severe form of type I reaction
- Deficiencies in the terminal components of complement increase the risk of meningococcal disease ✓ Correct
- Graves' disease is caused by a type IV reaction
- Serum sickness is caused by a type II reaction
- Urticaria usually responds to cimetidine

Serum sickness is due to circulating antibody-antigen complexes (type III).

Graves' disease is due to stimulating antibody (type V).

The most severe variety of type I reaction is anaphylaxis, with angio-oedema an intermediate reaction associated with wheeze and swelling of the lips and severe urticaria. These reactions are mediated by histamine 1 receptor stimulation.

Congenital C1 inhibitor deficiency is also caused by hereditary angio-oedema. Deficiencies in C1r, s, and 2-4 result in vasculitides; while deficiencies in C2, 3 and 5-8 are associated with an increased risk of septicaemia.

Work Smart Session - MRCP Part 1

Time taken: 40 mins 47 secs

Question: 17 of 100

Which of the following statements concerning abnormalities of the haemoglobin molecule is true?

(Please select 1 option)

- **A** Alpha thalassaemia is due to a deficiency of beta-chain production
- **B** HbS is caused by a single base mutation on the beta-chain
- **C** Genes for the alpha and beta chains are located on the same chromosome
- **D** In thalassaemia, persistence of HbF is an adverse prognostic sign
- **E** Oligonucleotide probes may assist in the diagnosis of haemoglobinopathies in adolescents

Work Smart Session - MRCP Part 1

Time taken: 42 mins 13 secs

Question: 17 of 100

Which of the following statements concerning abnormalities of the haemoglobin molecule is true?

(Please select 1 option)

- **A** Alpha thalassaemia is due to a deficiency of beta-chain production ✕ Incorrect answer selected
- **B** HbS is caused by a single base mutation on the beta-chain ← This is the correct answer
- **C** Genes for the alpha and beta chains are located on the same chromosome
- **D** In thalassaemia, persistence of HbF is an adverse prognostic sign
- **E** Oligonucleotide probes may assist in the diagnosis of haemoglobinopathies in adolescents

A Alpha thalassaemia is due to abnormalities of the alpha chain. Persistence of HbF has survival advantages in severely affected subjects.

C Alpha is located on 16, beta on 11.

E Hb electrophoresis are used in the adult, rather than oligonucleotide probes as used in the fetus.

Work Smart Session - MRCP Part 1

Time taken: 43 mins 26 secs

Question: 18 of 100

Which of the following is true of BCG vaccination?

(Please select 1 option)

- A Is a killed polysaccharide antigen vaccine
- B Is contraindicated in neonates
- C Is presently routinely offered in the UK at age 16 years
- **D Provides protection against leprosy** ✓ Correct
- E Should be given to all children who have a strongly positive tuberculin test

A The BCG vaccine is an attenuated strain; it provides approximately 70% protection.

B BCG vaccine may given to newborns at high risk of exposure.

C BCG is given at comprehensive school entry (age 11-13).

D It has also found a use in stimulating the immune system for the treatment of some cancers.

E It should not be given to these children. A low reactivity Heaf test (grade 0-1) should be documented before administration.

Work Smart Session - MRCP Part 1

Time taken: 43 mins 26 secs

Question: 19 of 100

A 17-year-old primigravida complains of constipation and arthralgia at 28 weeks' gestation.

A number of biochemical investigations are performed, but which of these are clinically significant?

(Please select 1 option)

- Detectable urinary human chorionic gonadotrophin
- Free thyroxine 8.9 pmol/l (9-22)
- Prolactin of 1000 mU/l (<450)
- Serum alkaline phosphatase of 350 iu/l (50-110)
- Serum corrected calcium 2.89 mmol/l (2.2-2.6)

Work Smart Session - MRCP Part 1

Time taken: 46 mins 29 secs

Question: 19 of 100

A 17-year-old primigravida complains of constipation and arthralgia at 28 weeks' gestation.

A number of biochemical investigations are performed, but which of these are clinically significant?

(Please select 1 option)

○	Detectable urinary human chorionic gonadotrophin
◉	Free thyroxine 8.9 pmol/l (9-22) ✕ Incorrect answer selected
○	Prolactin of 1000 mU/l (<450)
○	Serum alkaline phosphatase of 350 iu/l (50-110)
○	Serum corrected calcium 2.89 mmol/l (2.2-2.6) ← This is the correct answer

This patient has symptoms suggestive of hypercalcaemia, which are clinically significant.

Free thyroxine (T_4) is at the lower end of the normal range which is often the case in pregnancy and thyroid-stimulating hormone (TSH) is a better guide of thyroid function.

Hyperprolactinaemia is a normal finding in pregnancy, as is detectable urinary human chorionic gonadotrophin.

It is also normal for serum alkaline phosphatase to rise by up to four times normal due to increased placental production.

Work Smart Session - MRCP Part 1

Time taken: 1 mins 53 secs

Question: 1 of 100

Regarding gamma glutamyl transferase (GGT), which of the follwoing statements is false?

(Please select 1 option)

- A GGT in serum originates mainly from the liver
- B GGT is a sensitive marker of alcohol intake ← This is the correct answer
- C GGT levels are higher in patients of African ancestry
- D Most of the GGT in a cell is contained in the cell membrane ✕ Incorrect answer selected
- E Renal tissue has the highest concentration of the GGT enzyme

GGT is an enzyme which transfers a gamma glutamyl group between substances, especially between amino acids. It is found in many different types of tissue with the highest levels to be found in the proximal renal tubules. Serum GGT appears to come mostly from the liver and hepatobiliary system. GGT levels are higher in patients of African ancestry - the reason for this is unclear. Most of the GGT in the cell is incorporated into the cell membrane although some is also to be found in the cytoplasm. It may also be involve in transporting glutamyl-containing peptides across the cell membrane.

GGT is often used as a marker for alcohol intake but it is not sensitive or specific in this role. Some patients with heavy alcohol intake will have a GGT within the reference range and there are many causes of an elevated GGT - not just alcohol. GGT can be elevated with many drugs and toxins, cholestasis, viral hepatitis and pancreatitis. In some patients with acute myocardial infarction, GGT can raise after 3-4 days. The highest levels of GGT are usually seen with hepatobiliary disease.

Work Smart Session - MRCP Part 1

Time taken: 47 mins

Question: 20 of 100

Which of the following determines the primary mechanical properties of skin?

(Please select 1 option)

- Dermis
- Stratum basale
- Stratum corneum ✓ Correct
- Stratum granulosum
- Subcutaneous tissue

The stratum corneum is the last layer and provides a mechanical barrier to the skin and therefore determines the mechanical functions of the skin. The hands and feet have thick stratum corneum as compared to the lips and eyelids. The thicker the stratum corneum is the more protection there is for the skin.

The dermis also has some factor to play with its elastic fibres and fibrous tissue.

The rest of the layers are also important but the mechanical properties are primarily determined by the stratum corneum.

Work Smart Session - MRCP Part 1

Time taken: 48 mins 1 secs

Question: 21 of 100

Which of the following is true of autosomal dominant breast cancer?

(Please select 1 option)

- Autosomal dominant breast cancer affects females but not males
- BRCA 2 mutations increase the risk of prostate cancer ← This is the correct answer
- Females with the BRCA1 mutation will develop breast cancer
- It accounts for nearly half of all breast cancer cases in the United States
- (●) Penetrance is close to 100%, with nearly all gene carriers developing breast cancer by age 80 ✕ Incorrect answer selected

An estimated 5-10% of breast cancers are inherited.

Autosomal dominant inheritance is the main means of inheritance and the BRCA1 and BRCA2 mutations are two such genes.

BRCA1 is also associated with increased risk of pancreatic cancer, and BRCA2 is associated with pancreatic cancer, prostate cancer and melanoma.

It is important to remember that inheritance of these mutations leads to an increased risk of developing a malignancy, not the certainty of developing a malignancy.

Questions Set : REF29721
Page Safety Tools

Question: 22 of 100

A study reports on the results of a large study of the primary prevention of stroke in a diabetic population using a new antiplatelet agent versus aspirin.

The results of the study reveal that over a five year period the incidence of stroke in the aspirin treated group is 3%, compared to a rate of 1.5% in the group treated with the new antiplatelet agent (p <0.001).

What is the relative risk reduction in stroke associated with the new drug?

(Please select 1 option)

○	1.5%
○	15%
○	30%
◉	40% ✕ Incorrect answer selected
○	50% ← This is the correct answer

The relative risk reduction is an important calculation for the interpretation of publications.

In this case there is an absolute risk reduction of 1.5% (3 - 1.5%) in stroke afforded by the new agent compared with aspirin yet the relative risk reduction is 1.5 / 3 = 50%.

That is 50% fewer strokes may be prevented by the use of the newer agent compared with aspirin although this would be the equivalent of 15 per 1000 patients treated (30 strokes expected / 1000 patients treated with aspirin but only 15 with the new drug).

A 52-year-old man has been referred to the outpatient clinic due to deteriorating renal function.

A diagnosis of adult polycystic kidney disease (APKD) is made.

His family history reveals that his mother died of a stroke at the age of 50, and that his father is still alive. He is concerned regarding the inheritance of the disorder.

What is the probability that his son will inherit it?

(Please select 1 option)

○	0%
○	25%
◉	50% ✓ Correct
○	75%
○	100%

APKD is an autosomal dominant condition and typically presents between the ages of 30-50.

Patients develop deteriorating renal function and associated hypertension.

As well as renal cysts, they may also have hepatic and berry aneurysms (maternal history may be highly relevant here).

The chance of passing this condition to his son is 50%.

Work Smart Session - MRCP Part 1

Time taken: 52 mins 7 secs

Question: 24 of 100

A 53-year-old male presents with a three month history of polyuria with polydipsia.

Which of the following measurements would confirm a diagnosis of diabetes mellitus?

(Please select 1 option)

- A fasting plasma glucose of 6.5 mmol/L
- A fasting plasma glucose of 7.5 mmol/l
- A plasma glucose of 10 mmol/l at the end of an oral glucose tolerance test
- A random glucose of 10.5 mmol/l
- A urine dipstick analysis showing +++ glucose

Work Smart Session - MRCP Part 1

Time taken: 53 mins 40 secs

Question: 24 of 100

A 53-year-old male presents with a three month history of polyuria with polydipsia.

Which of the following measurements would confirm a diagnosis of diabetes mellitus?

(Please select 1 option)

- A fasting plasma glucose of 6.5 mmol/L
- A fasting plasma glucose of 7.5 mmol/l ✓ Correct
- A plasma glucose of 10 mmol/l at the end of an oral glucose tolerance test
- A random glucose of 10.5 mmol/l
- A urine dipstick analysis showing +++ glucose

Diabetes mellitus is diagnosed on the basis of symptoms plus a random glucose above 11.1 mmol/l or fasting plasma glucose above 7 mmol/l or the two hour oral glucose tolerance test (OGTT).

Impaired glucose tolerance would be indicated by a post OGTT plasma glucose between 7.7 and 11.1 or a fasting plasma glucose between 6.1 and 7.

Work Smart Session - MRCP Part 1

Time taken: 53 mins 40 secs

Question: 25 of 100

Mutation in which of the following is associated with Ehler-Danlos syndrome?

(Please select 1 option)

- Collagen type 1 gene
- FGFR3 gene
- Fibrillin- gene
- FMR-1 gene
- Type II procollagen gene

Collagen type 1 gene ← This is the correct answer

FGFR3 gene

Fibrillin- gene

FMR-1 gene ✕ Incorrect answer selected

Type II procollagen gene

Mutations in the following genes cause Ehlers-Danlos syndrome:

- ADAMTS2
- COL1A1
- COL1A2
- COL3A1
- COL5A1
- COL5A2
- PLOD1
- TNXB.

Ehlers-Danlos occurs in 1:5000 people world-wide.

In view of the wide number of mutations that can cause Ehlers-Danlos syndrome, this is a very heterogeneous condition.

FGFR3 is implicated in achondroplasia; fibrillin gene in Marfan's syndrome; and FMR-1 gene fragile X mental retardation 1.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 19 secs

Question: 26 of 100

A new rapid test is developed for the screening of leptospirosis.

Blood from 100 patients was analysed by the gold standard laboratory technique and by the new method. There were 20 positive results with the gold standard technique but there were 40 positive results using the new technique. The new technique correctly identified all cases that were later confirmed with the gold standard technique.

Approximately which of the following values reflects the positive predictive value of the new technique?

(Please select 1 option)

- 33%
- 50%
- 66%
- 75%
- 90%

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 5 mins 42 secs

Question: 26 of 100

A new rapid test is developed for the screening of leptospirosis.

Blood from 100 patients was analysed by the gold standard laboratory technique and by the new method. There were 20 positive results with the gold standard technique but there were 40 positive results using the new technique. The new technique correctly identified all cases that were later confirmed with the gold standard technique.

Approximately which of the following values reflects the positive predictive value of the new technique?

(Please select 1 option)

◉	33% ✕ Incorrect answer selected
○	50% ← This is the correct answer
○	66%
○	75%
○	90%

The positive predictive value is number of true positives/(no of true positives + false positives).

In the new technique there were 20 true positives and 20 false positives.

Thus the positive predictive value is 20/ (20 + 20) = 50%.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 10 mins 38 secs

Question: 27 of 100

Which of the following statements regarding the internal jugular vein and relations is true?

(Please select 1 option)

○	Lies lateral to the common carotid artery ← This is the correct answer
○	Originates at the carotid canal
○	Passes behind the clavicle to join the superior vena cava
◉	Passes posterior to the subclavian artery ✕ Incorrect answer selected
○	Receives a lymphatic trunk at its union with the external jugular vein.

The internal jugular vein originates at the jugular foramen.

It initially lies posterior to the carotid artery as it descends in the carotid sheath it lies lateral first to the internal then the common carotid artery within the carotid sheath.

It passes anterior to the subclavian artery to join the subclavian vein and then form the brachiocephalic vein; the left and right brachiocephalic veins unite to form the superior vena cava.

The internal jugular vein receives a lymphatic trunk at its union with the subclavian vein.

The external jugular vein drains into the subclavian vein.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 10 mins 38 secs

Question: 28 of 100

In a study of elderly patients with atrial fibrillation, patients receiving warfarin (n= 6000), 6% had strokes or died as a consequence of stroke, whereas in subjects treated with aspirin (n = 8000), 9 % had strokes or death from a stroke over the three year study period (p=0.001). The risk of stroke in an untreated population with atrial fibrillation over this time was 12%.

Which of the following percentages is the approximate annual incidence of stroke in the treated population in this study?

(Please select 1 option)

- 2.6%
- 3.3%
- 5.5%
- 6.9%
- 7.7%

Page Safety Tools

In a study of elderly patients with atrial fibrillation, patients receiving warfarin (n= 6000), 6% had strokes or died as a consequence of stroke, whereas in subjects treated with aspirin (n = 8000), 9 % had strokes or death from a stroke over the three year study period (p=0.001). The risk of stroke in an untreated population with atrial fibrillation over this time was 12%.

Which of the following percentages is the approximate annual incidence of stroke in the treated population in this study?

(Please select 1 option)

○	2.6% ← This is the correct answer
◉	3.3% ✕ Incorrect answer selected
○	5.5%
○	6.9%
○	7.7%

One needs to calculate the incidence as follows:

In the group treated with warfarin there were 360 strokes (6% of 6000).

In the aspirin treated group there were 720 strokes (9% of 8000).

Thus, there are 1080 strokes amongst the treated population (n=14000) over a three year time period.

Therefore there are 360 strokes annually in the treated group (14000) giving an annual incidence of stroke of approx 2.6%

Note: remember to divide by three since the study lasted three years and the figures given are for the three years incidence rates.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 24 mins 42 secs

Question: 29 of 100

In a study of 26,000 females, 1300 subjects were found to have either overt or subclinical hypothyroidism. Within this group, the risk of demonstrating either overt or subclinical hypothyroidism was therefore 5%.

What is the best descriptive term of this 5% risk?

(Please select 1 option)

- ○ Absolute risk
- ◉ Incidence ✕ Incorrect answer selected
- ○ Prevalence ← This is the correct answer
- ○ Relative risk
- ○ Specificity

This is the risk of either subclinical or overt hypothyroidism in a female population at any specific time which is the prevalence. This is defined as the rate of a disorder in a specified population at a specified time.

Incidence refers to the number of new cases of a disorder developing over a specific time.

A Ito (Stellate) cells

B Zone 1 hepatocytes ← This is the correct answer

C Kupffer cells ✕ Incorrect answer selected

D Zone 2 hepatocytes

E Zone 3 hepatocytes

The liver is made up of many small subunits called acini. Each acinus has a dual blood supply from firstly, a branch of the hepatic artery (oxygen rich) and secondly, a branch of the portal vein (solute rich). The blood from these flows though the hepatic sinusoids which allow quite free movement of solutes and oxygen from the blood cells into the hepatocytes. Eventually the blood joins a venule and drains into the hepatic vein and back to the systemic circulation.

Hepatocytes near the hepatic arterial supply and portal vein supply (periportal region) are called zone 1 hepatocytes. Zone 3 hepatocytes are furthest from the arterial supply and closest to the branch of the hepatic vein (perivenular region). Zone 2 hepatocytes are in the middle.

Zone 1 hepatocytes receive an oxygen-rich, solute-rich supply which makes them highly metabolically active, but more at risk of damage through the effects of toxins coming from the gut. Most of the highly-oxygen-requiring reactions occur here, including the electron transport chains, Krebs' cycle, fatty acid oxidation and urea synthesis. Zones 2 and 3 receive less oxygen and tend to be involved in reactions requiring little or no oxygen, such as glycolysis.

Ito cells store fats and Vitamin A and are involved in production of connective tissue. In liver disease, they are thought to be fundamental in the development of fibrosis and cirrhosis.

Kupffer cells are part of the reticuloendothelial system and are specialised macrophages. They are involved in the breakdown of haemoglobulin and the removal of haem for further metabolism in the hepatocytes. Kupffer cells also have a role in immunity.

A new test is developed for the diagnosis of HIV.

Blood from 10,000 patients was analysed by the gold standard technique and by the new method. There were 100 positive results with the gold standard technique but there were 150 positive results using the new technique.

Approximately which of the following values reflects the positive predictive value of the new technique?

(Please select 1 option)

○	33%
○	50%
◉	66% ✕ Incorrect answer selected
○	75%
○	90%
○	It cannot be determined ← This is the correct answer

The positive predictive value is number of true positives/(no of true positives + false positives).

There are 100 people tested positive with gold standard. However, we don't know how many of these are tested positive and how many are tested negative by the new techniques. Similarly, we don't know the number of people tested positive or negative aby the gold standard mong the 150 people tested positive by the new technique. Therefore, the number of true positives and false positives and hence the positive predictive value cannot be determined.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 28 mins 29 secs

Question: 31 of 100

Mutation in which of the following is associated with Marfan's syndrome?

(Please select 1 option)

○	Collagen type 1 gene
○	Collagen type 5 gene
◉	Fibrillin-1 gene ✓ Correct
○	FMR-1 gene
○	Type II procollagen gene

Mutation in the fibrillin-1 gene is thought to be responsible for Marfan's syndrome.

In Marfan's syndrome the lack of normal fibrillin-1 leads to overactivity of transforming growth factor type beta (TGF-b) in the wall of the aorta and the heart valves, leading to damage and destruction to the connective tissue which weakens that aortic wall and heart valves causing them to stretch.

Type 1 collagen gene defects are found in osteogenesis imperfecta and type 3 in Ehlers-Danlos syndrome.

Type II procollagen defect is found in hereditary spodyloarthropathy.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 28 mins 29 secs

Question: 32 of 100

A large multi-centre secondary prevention study reports a reduction in the annual incidence of recurrent subarachnoid haemorrhage from 10% in a medically treated group versus 6% in the group treated with medical therapy plus radiological intervention ($p<0.005$). The additional cost of the new treatment is £3000 per patient.

In the first year of treatment, what would be the predicted additional cost of preventing a single recurrent subarachnoid haemorrhage?

(Please select 1 option)

- ○ £3000
- ○ £12000
- ○ £30000
- ○ £75000
- ○ £90000

Question: 32 of 100

A large multi-centre secondary prevention study reports a reduction in the annual incidence of recurrent subarachnoid haemorrhage from 10% in a medically treated group versus 6% in the group treated with medical therapy plus radiological intervention ($p<0.005$). The additional cost of the new treatment is £3000 per patient.

In the first year of treatment, what would be the predicted additional cost of preventing a single recurrent subarachnoid haemorrhage?

(Please select 1 option)

○	£3000
◉	£12000 ✕ Incorrect answer selected
○	£30000
○	£75000 ← This is the correct answer
○	£90000

This study shows that annual rate of recurrent subarachnoid haemorrhage is reduced from 10% to 6%.

Therefore, if you treated 100 patients for one year you would expect 10 patients with subarachnoid haemorrhage in the medically treated group versus six patients in the medical plus radiological intervention group - a reduction of four patients per hundred.

Therefore you would need to treat 25 patients (4/100) to expect one less case of subarachnoid haemorrhage.

Thus the extra cost of this would be 25 x 3000 = £75000.

Question: 33 of 100

Where does RNA splicing occur?

(Please select 1 option)

○	Cytoplasm
○	Endoplasmic reticulum
○	Mitochondria
○	Nucleus ← This is the correct answer
◉	Ribosome ✕ Incorrect answer selected

Coding sequence is interrupted by non-coding sequences.

Removal of the introns in RNA transcript modification is called RNA splicing.

Splicing occurs in the nucleus before transport to the cytoplasm.

Exons are expressed sequences: these sequences are those present in mature mRNA.

Question: 34 of 100

Which of the following is typically elevated in Gaucher's disease?

(Please select 1 option)

◉	Acid phosphatase ✓ Correct
○	Alkaline phosphatase
○	Amylase
○	Glucocerebrosidase
○	Lipase

Gaucher's disease is the most frequent of the lysosomal storage diseases.

The condition is usually due to a catalytic deficiency of glucocerebrosidase. It is accompanied by many ill-understood plasma and metabolic abnormalities. These include a polyclonal immunoglobulin response that may progress to monoclonal gammopathy, amyloidosis, or even frank myeloma.

Low-density lipoprotein (LDL) and high-density lipoprotein (HDL) cholesterol fractions are abnormal in the plasma.

Some lysosomal enzymes are elevated including tartrate-resistant acid phosphatase, hexosaminidase, and a human chitinase, chitotriosidase. This latter enzyme has proved to be very useful for monitoring Gaucher's disease activity in response to treatment and may reflect the severity of the disease.

Histology positive	40	10
Histology negative	50	900

To what does the specificity approximate?

(Please select 1 option)

○	50%
○	60%
○	70%
◉	80% ✕ Incorrect answer selected
○	90% ← This is the correct answer

Sensitivity relates to the probability that the person with a disease will be correctly identified with the disease.

Therefore in this study 50 subjects have adrenal carcinoma of whom 40 are correctly identified with the disease giving a sensitivity of 80%.

The specificity is the probability that a person without the disease will be correctly identified by the test.

In this case there are 950 subjects without adrenal carcinoma of whom 900 were identified by the test - giving a specificity of ~95%.

Summary of sensitivity and specificity as defined by contingency tables.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 40 mins 58 secs

Question: 36 of 100

Which of the following has been shown to increase the risk of prostate cancer?

(Please select 1 option)

○	Caucasian race
◉	Exposure to cadmium ✓ Correct
○	Family history of colon cancer
○	Low intake of animal fats
○	Occupational exposure to dust

Black ethnicity is associated with a higher risk of prostate cancer than white.

A family history of breast cancer increases the risk of prostate cancer, as does a family history of prostate cancer.

An occupation in farming also seems to increase the risk of prostate cancer.

High intake of animal fats, and low selenium intake, as well as exposure to radiation and cadmium all increase the risk of prostate cancer.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 40 mins 58 secs

Question: 37 of 100

A 45-year-old female attends clinic complaining of tiredness. She is hypothyroid and takes thyroxine 150 micrograms daily.

Which of the following is the most useful test for assessing the appropriateness of thyroid hormone replacement in primary hypothyroidism?

(Please select 1 option)

- Free T3 and T4 concentrations
- Skin biopsy
- Thyroid binding globulin
- Total T3 and T4
- TSH

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 41 mins 51 secs

Question: 37 of 100

A 45-year-old female attends clinic complaining of tiredness. She is hypothyroid and takes thyroxine 150 micrograms daily.

Which of the following is the most useful test for assessing the appropriateness of thyroid hormone replacement in primary hypothyroidism?

(Please select 1 option)

○	Free T3 and T4 concentrations
○	Skin biopsy
○	Thyroid binding globulin
○	Total T3 and T4
◉	TSH ✓ Correct

Thyroid-stimulating hormone (TSH) has been recognised as an exquisitely sensitive indicator of thyroid status.

A normal TSH result suggests adequate thyroid hormone replacement and euthyroidism.

Similarly elevated TSH with normal thyroid hormone concentrations would suggest poor compliance and suppressed TSH with normal high thyroxine (T4) suggests over-replacement.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 42 mins 22 secs

Question: 38 of 100

Which of the following is most likely to be reversible following venesection in a 45-year-old male with haemochromatosis?

(Please select 1 option)

- Arthropathy
- Cardiomyopathy ✓ Correct
- Cirrhosis
- Diabetes mellitus
- Hypopituitarism

Disorders that are potentially reversible in haemochromatosis include the dermal pigmentation and cardiomyopathy.

Similarly there are improvements in liver function tests.

However, diabetes, cirrhosis, hypogonadism and arthropathy are usually irreversible.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 42 mins 22 secs

Question: 39 of 100

It has been suggested that cystic fibrosis (CF) (autosomal recessive) has a high prevalence in some populations because heterozygotes are resistant to the effects of chloride-secreting diarrhoea. This is best described as an example of:

(Please select 1 option)

- Gene flow
- Genetic drift
- Linkage disequilibrium
- Mutation
- Natural selection

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 43 mins 30 secs

Question: 39 of 100

It has been suggested that cystic fibrosis (CF) (autosomal recessive) has a high prevalence in some populations because heterozygotes are resistant to the effects of chloride-secreting diarrhoea. This is best described as an example of:

(Please select 1 option)

- Gene flow
- Genetic drift
- Linkage disequilibrium
- Mutation
- Natural selection ✓ Correct

Natural selection is the likely explanation as it appears that heterozygous for CF may offer some protection against diarrhoeal illnesses particularly typhoid.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 43 mins 30 secs

Question: 40 of 100

Which is a likely explanation for the high prevalence of cystic fibrosis in European populations?

(Please select 1 option)

- Heterozygotes may have an advantage because of increased resistance to cholera.
- Inbreeding is common among Europeans.
- Many different mutations can cause cystic fibrosis.
- Most of the disease genes are hidden in heterozygotes.
- The locus has a high mutation rate.

Which is a likely explanation for the high prevalence of cystic fibrosis in European populations?

(Please select 1 option)

◉	Heterozygotes may have an advantage because of increased resistance to cholera. ✓ Correct
○	Inbreeding is common among Europeans.
○	Many different mutations can cause cystic fibrosis.
○	Most of the disease genes are hidden in heterozygotes.
○	The locus has a high mutation rate.

The prevalence of the cystic fibrosis gene at around 1 in 20 of the population would suggest that this provides some evolutionary survival advantage. Like sickle cell trait offering a survival advantage to malaria, it is believed that the cystic fibrosis gene offers a possible survival advantage against cholera and enteropathogenic bacteria.

"Cholera opens chloride channels, letting chloride and water leave cells. The CFTR protein does just the opposite, closing chloride channels and trapping salt and water in cells, which dries out mucus and other secretions. A person with CF cannot contract cholera, because the toxin cannot open the chloride channels in the small intestine.

Carriers of CF enjoy the mixed blessing of a balanced polymorphism. They do not have enough abnormal chloride channels to cause the labored breathing and clogged pancreas of cystic fibrosis, but they do have enough of a defect to prevent the cholera from taking hold. During the devastating cholera epidemics that have peppered history, individuals carrying mutant CF alleles had a selective advantage, and they disproportionately transmitted those alleles to future generations. However, because CF arose in Western Europe and cholera in Africa, perhaps an initial increase in CF herterozygosity was a response to a different diarrheal infection." (Read more about balanced polymorphism).

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 44 mins 53 secs

Question: 41 of 100

A 65-year-old man with a history of myocardial infarction four years earlier was admitted with sudden onset shortness of breath, decreasing exercise tolerance and pedal oedema.

He takes lansoprazole, aspirin, furosemide and lisinopril.

Which of the following laboratory tests would identify the reason for his acute presentation?

(Please select 1 option)

- Brain natriuretic peptide (BNP)
- Clotting screen
- C reactive protein
- Full blood count
- Urea and electrolytes

A 65-year-old man with a history of myocardial infarction four years earlier was admitted with sudden onset shortness of breath, decreasing exercise tolerance and pedal oedema.

He takes lansoprazole, aspirin, furosemide and lisinopril.

Which of the following laboratory tests would identify the reason for his acute presentation?

(Please select 1 option)

◉	Brain natriuretic peptide (BNP) ✓ Correct
○	Clotting screen
○	C reactive protein
○	Full blood count
○	Urea and electrolytes

This patient has features of heart failure which appear to be related to underlying ischaemic heart disease.

BNP is synthesised in the cardiac ventricles and correlates with left ventricle (LV) pressure, degree of dyspnoea, and state of neurohormonal modulation. Thus BNP is the first potential marker for heart failure.

Measurement of plasma BNP concentration is evolving as a very efficient and cost effective mass screening technique for identifying patients with various cardiac abnormalities regardless of etiology and degree of LV systolic dysfunction.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 47 mins 18 secs

Question: 42 of 100

A patient presents with acute promyelocytic leukaemia (APL).

What is the likely mechanism underlying leukaemogenesis?

(Please select 1 option)

○	Aberrant fusion of 2 genes ← This is the correct answer
○	Impaired protein degradation
◉	Over expression of cellular oncogene ✕ Incorrect answer selected
○	Post-translational modification
○	Telomere shortening

In APL one of the retinoic acid receptor genes, RARA, is fused to PML in the great majority of patients as a result of the chromosomal translocation t(15; 17).

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 47 mins 18 secs

Question: 43 of 100

A publication reports the outcome of a new statin therapy in a placebo controlled primary prevention of ischaemic heart disease in a diabetic population.

1000 patients were randomised to receive the new therapy and 1000 allocated to placebo. The study was completed over a five year period.

In the placebo group there were 150 myocardial infarcts (MI) and in the group treated with the new statin there were 100 infarcts.

What is the relative risk reduction of MI afforded by statin therapy?

(Please select 1 option)

- ○ 15%
- ○ 25%
- ○ 33%
- ○ 40%
- ○ 50%

Work Smart Session - MRCP Part 1

Question: 43 of 100

A publication reports the outcome of a new statin therapy in a placebo controlled primary prevention of ischaemic heart disease in a diabetic population.

1000 patients were randomised to receive the new therapy and 1000 allocated to placebo. The study was completed over a five year period.

In the placebo group there were 150 myocardial infarcts (MI) and in the group treated with the new statin there were 100 infarcts.

What is the relative risk reduction of MI afforded by statin therapy?

(Please select 1 option)

○	15%
◉	25% ✕ Incorrect answer selected
○	33% ← This is the correct answer
○	40%
○	50%

There are 50 fewer MIs in the treated group than the placebo treated group, hence 50/150=33%.

The relative risk reduction provides information regarding the efficacy of a therapy and what reduction in risk may be expected when treating subjects rather then just having data relating to the significance of the data.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 51 mins 6 secs

Question: 44 of 100

A 17-year-old female presents after taking an overdose of her grandmother's medication.

Investigations revealed a serum potassium of 6 mmol/L (3.5-4.9).

Which one of the following drugs is the most likely cause of this abnormality?

(Please select 1 option)

○	Aspirin
○	Digoxin
○	Fluoxetine
○	Omeprazole
◉	Propranolol ✓ Correct

Betablockers, particularly propranolol, in overdose can cause hyperkalaemia by transmembrane shifts. It is useful to think of the opposite - beta-agonists such as salbutamol are far more widely known to cause hypokalaemia.

Overdose of digoxin therapy most commonly manifests as rhythm disturbance and may be exacerbated by hyper- or hypokalaemia.

Salicylate overdose causes metabolic acidosis and respiratory alkalosis.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 52 mins 41 secs

Question: 45 of 100

A 28-year-old man presented with hypertension.

On examination he had palpable kidneys and abdominal ultrasound shows bilaterally enlarged cystic kidneys.

Which one of the following conditions is most likely to be present in this patient?

(Please select 1 option)

○	Mitral stenosis
○	Nail dystrophy
◉	Polycythaemia ✓ Correct
○	Short stature
○	Testicular atrophy

The most likely diagnosis here is adult polycystic kidney disease, which is associated with valvular heart abnormalities, incompetence and aneurysms of the cerebral circulation.

However, it is also associated with excessive erythropoietin production and polycythaemia.

Questions Set : REF7558
Page Safety Tools

Intravenous urogram

Isotope renography

Renal ultrasound ✓ Correct

Urinalysis

The answer lies between renal ultrasound and genetic linkage analysis. Polycystic kidney disease is an autosomal dominant disorder. Mutations in at least three different genes can lead to autosomal dominant polycystic disease (APKD).

1. PKD-1 on chromosome 16: 85% of cases. Polycystin 1 is an integral membrane glycoprotein involved in cell/matrix interactions
2. PKD-2 on chromosome 4: 10% of cases. Polycystin 2 which may associate with polycystin 1 through a common signalling pathway
3. A third gene mutation is known but its exact chromosomal location is not.

Diagnosis is made by multiple bilateral renal cysts and a positive family history.

Genetic linkage studies: Can exclude or make the diagnosis in younger patients. Requires blood from at least two affected family members.

Ultrasonography:

- In PKD 1 families, age related diagnostic criteria are used: two cysts in under 30 years age group.
- At least two cysts in each kidney in 30-59 years. Four cysts in each kidney for over 60 years.

CT: More sensitive than USS and may aid in diagnosis in younger patients.

MR angiography: In patients with a family history of intracranial aneurysm - to screen for cerebral aneurysms.

Question: 47 of 100

In a trial of statin therapy in the secondary prevention of ischaemic heart disease, therapy is shown to reduce cardiovascular mortality from 12% to 8% over the five years duration of the study.

In comparison with standard therapy, what is the number of patients that need to be treated to prevent one death over five years?

(Please select 1 option)

○	5
○	10
◉	20 ✕ Incorrect answer selected
○	25 ← This is the correct answer
○	50

The drug has reduced the risk of death post myocardial infarction (MI) by 4% over five years.

Therefore if 100 people were treated we could expect the prevention of four deaths.

Therefore in order to prevent one death, 25 individuals would need to treated.

A 79-year-old woman presents with mild dyspnoea and confusion. Of note in her past medical history was a one year history of Raynaud's phenomenon.

On examination her pulse was 118 beats per minute, she had a blood pressure of 122/88 mmHg and she had a small ulcer on her right big toe.

Auscultation of her chest revealed bibasal crackles and she had mild ankle oedema.

Her investigations show:

Haemoglobin	9.5 g/dl	(11.5-16.5)
White cell count	3.5 x 10^9/l	(4-11)
Platelet count	110 x 10^9/l	(150-400)
Serum total protein	120 g/l	(61-76)

Serum immunoglobulins:

IgA	0.8 g/l	(0.8-3.0)
IgG	15 g/l	(6.0-13.0)
IgM	70 g/l	(0.4-2.5)

Which of the following complications is she likely to develop?

(Please select 1 option)

- Acute renal failure

○	Hyperviscosity syndrome ← This is the correct answer
◉	Pathological bone fracture ✕ Incorrect answer selected

This elderly woman has a very raised IgM level, pancytopenia, Raynaud's phenomenon and a foot ulcer.

The most likely diagnosis here is Waldenström's macroglobulinaemia (WM). WM refers to a condition that presents in the seventh or eighth decade of life.

It is characterised by the presence of a high level of a macroglobulin (immunoglobulin M [IgM]), elevated serum viscosity and the presence of a lymphoplasmacytic infiltrate in the bone marrow, resulting in pancytopenias.

Raynaud's phenomenon may herald the onset of this condition and is due to cryoglobulinaemia.

The monoclonal IgM causes

- Hyperviscosity syndrome
- Cryoglobulinaemia types 1 and 2
- Coagulation abnormalities
- Polyneuropathies
- Cold agglutinin disease and anaemia
- Primary amyloidosis
- Tissue deposition of amorphous IgM in skin, the gastrointestinal tract, kidneys, and other organs.

Time taken: 2 hrs 5 mins 47 secs

Question: 49 of 100

A 51-year-old woman presented with nocturia and pruritis vulvae.

Investigations revealed:

Urine dipstick analysis	glucose 2%

Which one of he following would most reliably confirm a diagnosis of diabetes mellitus?

(Please select 1 option)

- 50 g oral glucose tolerance test
- Elevated glycated haemoglobin concentration
- Fasting plasma glucose of 6.7 mmol/L (3.0-6.0)
- Random plasma glucose of 8.3 mmol/L
- Two hour post-prandial plasma glucose of 12 mmol/L (<11.1)

Investigations revealed:

Urine dipstick analysis	glucose 2%

Which one of he following would most reliably confirm a diagnosis of diabetes mellitus?

(Please select 1 option)

- ○ 50 g oral glucose tolerance test
- ○ Elevated glycated haemoglobin concentration
- ○ Fasting plasma glucose of 6.7 mmol/L (3.0-6.0)
- ○ Random plasma glucose of 8.3 mmol/L
- ◉ Two hour post-prandial plasma glucose of 12 mmol/L (<11.1) ✓ Correct

The post-prandial glucose gives an equivalent to the 75 g glucose tolerance test which would be one of the investigations of choice in this patient.

None of the other results listed here formally confirm the diagnosis of type 2 diabetes.

Work Smart Session - MRCP Part 1

Time taken: 5 mins 4 secs

Question: 4 of 100

What is the mechanism of action of glycopeptides (e.g. vancomycin)?

(Please select 1 option)

- **A** Cell wall inhibition ✓ Correct
- **B** Inhibition of protein synthesis (translation)
- **C** Inhibition of protein synthesis (transcription)
- **D** Inhibition of folic acid metabolism
- **E** Interference with DNA replication

Glycopeptides inhibit cell wall synthesis through steric hindrance of peptidoglycans, components of the bacterial cell wall.

Work Smart Session - MRCP Part 1

Time taken: 5 mins 4 secs

Question: 5 of 100

The CAPRIE study looked at whether aspirin or clopidogrel was most appropriate in patients at increased risk of cardiovascular disease to prevent the MACE composite endpoint, which consists of stroke, MI or cardiovascular death, re-hospitalisation or bleeding.

A substudy looked at 3,866 patients with a history of diabetes and found an event rate of 17.7% for patients taking aspirin, versus 15.6% for patients taking clopidogrel.

What is the number needed to treat (NNT) to prevent one event for patients taking clopidogrel versus aspirin?

(Please select 1 option)

- 2.1
- 15.6/17.7
- 100/2.1
- 100/15.6
- 100/17.7

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 6 mins 41 secs

Question: 50 of 100

A letter to a medical journal suggested that an established antidepressant may cause photosensitivity. The manufacturer wished to set up a study to determine rapidly and efficiently whether this was a true association.

Which one of the following techniques is most appropriate?

(Please select 1 option)

- A dose ranging study
- A case control study
- A double blind, randomised, placebo controlled study
- A meta-analysis
- A sequential trial

○	A double blind, randomised, placebo controlled study
◉	A meta-analysis ✓ Correct
○	A sequential trial

A sequential trial is one in which the data are analysed after each participant's results become available, and the trial continues until a clear benefit is seen in one of the comparison groups, or it is unlikely that any difference will emerge.

The main advantage of sequential trials is that they will be shorter than fixed length trials when there is a large difference in the effectiveness of the interventions being compared. Their use is restricted to conditions where the outcome of interest is known relatively quickly.

In a case control study, patients who have developed a disease are identified and their past exposure to aetiological factors is compared with that of controls who do not have the disease.

A double-blind randomised placebo controlled study does not seem appropriate in this case, and a dose-ranging study would be used in the early stages of drug development to identify common side effects, perhaps toxicity, and threshold efficacy doses.

The most appropriate study would probably be a meta-analysis. This is because:

- the drug is in the market place
- large studies will have taken place in order for it to obtain its license the data are available relatively rapidly (compared with the other options in this question)
- the analysis could be carried out efficiently (cheaply if one were being cynical), and
- the results of the trial would also be available rapidly.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 7 mins 35 secs

Question: 51 of 100

A 17-year-old girl presents with a two week history of urticaria.

Over the last couple of days she has been aware of new lesions occurring on a daily basis.

Which one of the following statements is most likely to be correct?

(Please select 1 option)

- She is likely to have an associated asthma
- She is likely to have taken penicillin recently
- She is unlikely to have any identifiable trigger factor
- The lesions will be present for at least 24 hours
- There is likely to be a nut allergy

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 8 mins 42 secs

Question: 51 of 100

A 17-year-old girl presents with a two week history of urticaria.

Over the last couple of days she has been aware of new lesions occurring on a daily basis.

Which one of the following statements is most likely to be correct?

(Please select 1 option)

◉	She is likely to have an associated asthma ✕ Incorrect answer selected
○	She is likely to have taken penicillin recently
○	She is unlikely to have any identifiable trigger factor ← This is the correct answer
○	The lesions will be present for at least 24 hours
○	There is likely to be a nut allergy

The commonest form of urticaria is idiopathic and there is no identifiable trigger.

Peanut allergy and penicillin may cause urticarial rashes but there is usually an associated specific history of contact with the allergen.

Urticarial lesions last less than 24 hours usually.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 9 mins 25 secs

Question: 52 of 100

Which of the following organelles contains enzymes responsible for the digestion of constituents of cells and tissues?

(Please select 1 option)

○	Endoplasmic reticulum
○	Golgi apparatus
◉	Lysosomes ✓ Correct
○	Microtubules
○	Mitochondria

The lysosomes contain the enzymes and molecules such as oxidases, free radical etc. responsible for the breakdown of intracellular components. Micortubules are involved in mitotic processes and intracellular transportation. The mitochondria produce energy for cellular functions.

○	Oestradiol
◉	PTH ✓ Correct
○	TRH
○	Triiodothyronine

Unlike steroids (progesterone, testosterone, oestradiol and cortisol) other ionic hormones such as:

- Adrenaline
- Growth hormone-releasing hormone (GHRH)
- Glucagon
- Luteinising hormone (LH)
- Follicle stimulating hormone (FSH)
- Parathyroid hormone (PTH)
- Thyroid-stimulating hormone (TSH)

are unable to pass the plasma membrane acting upon cell surface receptors and then through cyclic adenosine monophosphate (cAMP) as the second messenger.

Insulin acts through mitogen-activated protein (MAP) kinase pathway, as does growth hormone (GH) and prolactin.

- Thyroid releasing hormone (TRH)
- Gonadatrophin-releasing hormone (GnRH)
- Antidiuretic hormone (ADH)

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 13 mins 16 secs

Question: 55 of 100

A 75-year-old female presents with an acute stroke and is noted to have a partial left homonymous hemianopia, a mild left hemiparesis and left hemisensory inattention.

Where on the right is the most likely area of infarction?

(Please select 1 option)

- ○ Frontal lobe
- ○ Medial temporal lobe
- ○ Occipital lobe
- ◉ Parietal lobe ✓ Correct
- ○ Thalamus

Sensory inattention is caused by parietal lobe pathology.

Occipital lobe stroke usually causes isolated homonymous hemianopia.

Thalamic and frontal lobe infarcts do not cause visual field defects.

- It may present with migraine ✓ Correct
- Computerised tomography (CT) of the brain is diagnostic
- Death usually occurs in infancy
- The thalami are usually spared

CADASIL is a diffuse disease of small arteries, predominantly in the brain.

- It starts during mid adulthood and is characterised by:
-
- recurrent ischaemic events (transient or permanent)
- attacks of migraine with aura
- severe mood disorders
- sub-cortical dementia and
- a wide spread leukoencephalopathy on magnetic resonance imaging (MRI).
-
- CT brain is not diagnostic. Characteristic MRI changes include T2 .weighted hyperintensity of the periventricular white matter.
-
- A family history is almost always present, as it is an autosomal dominant condition, located to chromosome 19.
-
- Infarcts are subcortical, and the thalami and basal ganglia are usually involved.

Question: 58 of 100

A new publication describes a new test for cystic fibrosis.

You want to know what proportion of patients with cystic fibrosis would be correctly identified by this new test.

Which one of the following values would identify this?

(Please select 1 option)

○	Accuracy
○	Negative predictive value
○	Positive predictive value
◉	Sensitivity ✓ Correct
○	Specificity

The proportion of patients with the disease who would be identified by the new test is the sensitivity. This refers to the proportion with the disease who truly have cystic fibrosis and are identified as such by the test.

Positive predictive value refers to the percent of people having a positive test who actually have the disease interpreted in conjunction to the prevalence of the disease (true positives/true positives+false positives).

Safety
Tools

○	Cushing's syndrome
○	Hepatic failure
○	Pregnancy ← This is the correct answer
◉	Salicylate poisoning ✕ Incorrect answer selected

This patient has a mild metabolic alkalosis with what appears to be respiratory compensation as reflected by the elevated pCO_2.

Amitriptyline overdose is associated with acidosis as is salicylate poisoning.

Hepatic failure usually presents with acidosis.

This type of picture is associated with:

- prolonged vomiting (as in pregnancy)
- diarrhoea
- diuretic therapy
- Cushing's syndrome
- those receiving high dose corticosteroids.

With no other information provided for this case, common things being common, one should select pregnancy as the best answer for a 20-year-old female.

A substudy looked at 3,866 patients with a history of diabetes and found an event rate of 17.7% for patients taking aspirin, versus 15.6% for patients taking clopidogrel.

What is the number needed to treat (NNT) to prevent one event for patients taking clopidogrel versus aspirin?

(Please select 1 option)

○	2.1
○	15.6/17.7
○	100/2.1 ← This is the correct answer
◉	100/15.6 ✕ Incorrect answer selected
○	100/17.7

The number needed to treat to prevent one specified outcome event is 100 divided by the absolute risk reduction, in this case 17.7-15.6%= 2.1%. This equals 48, meaning that 48 patients need to be treated with clopidogrel versus aspirin to prevent one stroke, MI cardiovascular death, bleed or hospitalisation.

For many studies now, papers quote the number needed to harm. This uses the same principle to establish the difference in absolute risk of an adverse event occurring between two treatment strategies, calculating a number needed to harm by dividing 100 by the absolute risk.

Calculation of both number needed to treat and number needed to harm for a new therapy allows clinicians to establish net clinical benefit.

Further reading:
Comparative Benefits of Clopidogrel and Aspirin in High-Risk Patient Populations (pdf) Arch Intern Med. 2004;164:2106-2110

An 18-year-old male is diagnosed with Becker's muscular dystrophy.

Which of the following statements concerning the genetics of the condition is correct?

(Please select 1 option)

○	His brothers will all be affected
○	His daughters will have a 50% chance of being carriers
◉	His daughters' sons will have a 50% chance of having the disease ✓ Correct
○	His sons will be carriers of the condition
○	His sons' children will have a 50% chance of having the disease

Becker's muscular dystrophy is an X-linked condition and so 50% of males will be affected in a family.

His sons will get the X chromosome from his wife and so will not be carriers but all his daughters will be carriers.

However, his daughters' sons will consequently have a 50% chance of inheriting the disease as all his daughters are carriers and there is a one in two chance (50:50) of passing the gene onto their sons.

On the other hand his sons who are not affected do not pass on the condition.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 30 mins 6 secs

Question: 61 of 100

Which of the following would invalidate the use of the unpaired *t* test in the comparison of mean drug concentrations between two groups of subjects?

(Please select 1 option)

- Insufficient statistical power
- Non-normal distribution of data
- Small sample size
- Small standard error
- Unequal sample sizes in both groups

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 31 mins 11 secs

Question: 61 of 100

Which of the following would invalidate the use of the unpaired *t* test in the comparison of mean drug concentrations between two groups of subjects?

(Please select 1 option)

○	Insufficient statistical power
◉	Non-normal distribution of data ✓ Correct
○	Small sample size
○	Small standard error
○	Unequal sample sizes in both groups

The *t* test can only be used for parametric (normally distributed) data.

Insufficient statistical power as a consequence of numbers recruited would not invalidate the results of a *t* test.

It is probable that the results would be unlikely to show any difference with too few subjects, although it is possible that if the differences were large then irrespective of prior power calculations differences might be seen.

A 60-year-old male is brought to casualty in the early hours of the morning after being found unconscious in the street.

On examination, he was drowsy but localised to painful stimuli. There was no evidence of head injury or meningism.

Investigations revealed:

Sodium	134 mmol/l	(137-144)
Potassium	4.0 mmol/l	(3.5-4.9)
Urea	4.0 mmol/l	(2.5-7.5)
Creatinine	80 µmol/l	(60-110)
Glucose	4.5 mmol/l	(3.0-6.0)
Chloride	100 mmol/l	(95-107)
Bicarbonate	25 mmol/l	(20-28)
Plasma osmolality	385 mosmol/kg	(278-305)

What is the most likely explanation for his presentation?

(Please select 1 option)

- ○ Diazepam poisoning
- ○ Ethanol poisoning
- ○ Methanol poisoning

Bicarbonate	25 mmol/l	(20-28)
Plasma osmolality	385 mosmol/kg	(278-305)

What is the most likely explanation for his presentation?

(Please select 1 option)

- Diazepam poisoning
- Ethanol poisoning ← This is the correct answer
- Methanol poisoning ✕ Incorrect answer selected
- Phenobarbitone poisoning
- Phenytoin poisoning

This gent is intoxicated.

He has a normal acid base balance, slight hyponatraemia reflecting dilution, and very high osmolality reflecting the presence of ethanol.

Methanol would produce an acidosis.

Diazepam is not an osmolyte nor would the other agents produce this picture.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 35 mins 54 secs

Question: 63 of 100

Which of the following statements concerning iron metabolism is correct?

(Please select 1 option)

- Approximately 0.1% of body iron circulates in the plasma
- Approximately 90% of dietary iron is absorbed in the intestine
- The main route of excretion is the liver
- The serum ferritin concentration is reduced characteristically following surgery
- The transferrin content of intestinal mucosal cells is high when body iron stores are high

Question: 65 of 100

Which of the following statements concerning iron metabolism is correct?

(Please select 1 option)

○	Approximately 0.1% of body iron circulates in the plasma ← This is the correct answer
◉	Approximately 90% of dietary iron is absorbed in the intestine ✕ Incorrect answer selected
○	The main route of excretion is the liver
○	The serum ferritin concentration is reduced characteristically following surgery
○	The transferrin content of intestinal mucosal cells is high when body iron stores are high

Approximately 4 mg of iron circulate within the plasma with a total body iron store of 3-4 g (2500 mg in the RBCs, 500 mg in liver, 500 mg in macrophages and about 500 mg in muscle).

From an intake of approximately 6 mg/1000 kcal of dietary iron only 15% is bioavailable.

The majority of iron contained within the RBCs is metabolised and re-utilised but 1 mg per day is lost through the gut.

Ferritin, the plasma protein responsible for binding iron, is an acute phase reactant protein and increases in inflammatory conditions following surgery.

Transferrin is a glycoprotein responsible for internal iron exchange and the content within mucosal cells is naturally low in haemochromatosis with high saturation.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 38 mins 24 secs

Question: 64 of 100

A 65-year-old woman presented with a malabsorption syndrome.

She had a past history of radiotherapy for cervical cancer.

Small intestine biopsy reveals

- villous atrophy and crypt hypertrophy

- chronic inflammatory cell infiltrate of the lamina propria together with

- increase in intra-epithelial lymphocytes.

What is the most likely diagnosis?

(Please select 1 option)

○	Bacterial overgrowth
○	Coeliac disease
○	Crohn's disease
○	Mesenteric ischaemia
○	Radiation enteropathy

- increase in intra-epithelial lymphocytes.

What is the most likely diagnosis?

(Please select 1 option)

○	Bacterial overgrowth
◉	Coeliac disease ✓ Correct
○	Crohn's disease
○	Mesenteric ischaemia
○	Radiation enteropathy

Do not be put off by the description of the case; these histological features are typical of coeliac disease with

- villous atrophy

- crypt hyperplasia/hypertrophy

- inflammatory infiltrate of the lamina propria and

- intra-epithelial lymphocytes.

Useful serology includes anti-TTG antibodies which would be expected in over 90% of cases.

Treatment of this case would therefore entail gluten-free diet.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 49 mins 16 secs

Question: 65 of 100

A 43-year-old man has had vague malaise for three weeks.

Physical examination is normal, except for a blood pressure of 150/95 mmHg and pitting oedema of the legs to the knees.

Dipstick urinalysis shows no glucose, blood, ketones, nitrite, or urobilinogen, and the microscopic urinalysis reveals no RBC/hpf and only 1 WBC/hpf. Additional laboratory testing reveals a 24 hour urine protein of 4.1 gm. His serum creatinine is 350 µmol/L (60-110) with urea of 30 mmol/L (2.5-7.5). His hepatitis B surface antigen is positive.

Which of the following conditions is he most likely to have?

(Please select 1 option)

- Acute tubular necrosis
- Diabetic nephropathy
- Membranous glomerulonephritis
- Post-streptococcal glomerulonephitis
- Systemic lupus erythematosus

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 8 mins 1 secs

Question: 66 of 100

A new diagnostic test for malabsorption has been analysed and the results have yielded the following 2x2 contingency table.

	Disease present	
test result	yes	no
+ve	0.9	0.1
-ve	0.2	0.8

Applying this test to a case of chronic diarrhoea from a patient group where the prevalence of malabsorption is known to be 20% (probability = 0.2) what is the probability of a patient having malabsorption if they have a positive test?

(Please select 1 option)

- 0.16
- 0.24
- 0.48
- 0.64
- 0.8

0.8 ✕ Incorrect answer selected

This is tough but the College are putting more and more Evidence Based Medicine Questions into the exam. This question tests understanding of pre-test and post-test odds, likelihood ratios, sensitivity and specificity. The calculation is as follows.

Sensitivity = 0.9/(0.9 + 0.2) = 0.818

Specificity = 0.8 / (0.1 + 0.8) = 0.889

Likelihood ratio for a postivie test (LR+) = 0.818 / (1 - 0.889) = 7.2

Pre-test **odds** = 0.2 / (1 - 0.2) = 0.25

Post-test odds = pre-test odds X LR+ = 0.25 X 7.2 = 1.8

Post-test **probability** = 1.8 / (1.8 + 1) = 0.64

	Disease present	
test result	yes	no
+ve	true positive (A)	false positive (B)
-ve	false negative (C)	true negative (D)

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 11 mins 6 secs

Question: 67 of 100

A study of a new chemotherapy drug for lung cancer is reported in a medical journal. The authors state that with the new agent the five year mortality rate was 60%. Without treatment the five year mortality rate was 80%.

Which of the following represents the absolute risk reduction using this treatment?

(Please select 1 option)

- ○ 10%
- ○ 20%
- ○ 25%
- ◉ 33%
- ○ 40%

Which of the following represents the absolute risk reduction using this treatment?

(Please select 1 option)

○	10%
○	20% ← This is the correct answer
○	25%
◉	33% ✕ Incorrect answer selected
○	40%

The absolute risk reduction is an important figure and should always be quoted instead of the the relative risk reduction.

Examples: If a drug reduces the incidence of heart attacks from 10% to 5% then:

- The control event rate (CER) is 10%
- The experimental event rate (EER) is 5%
- The relative risk reduction (RRR) is 50%
- The absolute risk reduction (ARR) is 5%
- The number needed to treat (NNT) is 100% / 5% = 20.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 25 mins 10 secs

Question: 68 of 100

Concerning complete atrioventricular septal defects which one of the following statements is true?

(Please select 1 option)

◉	Are seen frequently in patients with trisomy 21 ✓ Correct
○	Frequently have aortic valve (AV) insufficiency
○	Have a normal mitral valve structure
○	Include a coronary sinus atrial septal defect (ASD)
○	Include a perimembranous ventricular septal defect

Partial AV canal defects or ostium primum ASDs are seen in Down syndrome.

Sinus venous defects seem to be rare in Down syndrome.

Possibly 50% of children with Down syndrome have a cardiac defect.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 25 mins 10 secs

Question: 69 of 100

You are asked to see a patient in the intensive care unit who is short of breath and tachycardic to rule out a cardiac cause of her symptoms.

A right heart catheter reveals that the mixed venous O_2 saturation is 70%; the pulmonary capillary wedge O_2 saturation is 97%. The haemoglobin is normal and the patient is afebrile.

Which of the following is the most appropriate statement that could be applied to her features?

(Please select 1 option)

- Her cardiac output is decreased
- Her cardiac output is normal
- Her heart is normal
- She has high-output failure
- She is in shock due to a non-cardiac cause

Submit answer | Skip question | Remove question

You are asked to see a patient in the intensive care unit who is short of breath and tachycardic to rule out a cardiac cause of her symptoms.

A right heart catheter reveals that the mixed venous O_2 saturation is 70%; the pulmonary capillary wedge O_2 saturation is 97%. The haemoglobin is normal and the patient is afebrile.

Which of the following is the most appropriate statement that could be applied to her features?

(Please select 1 option)

- Her cardiac output is decreased
- Her cardiac output is normal ✓ Correct
- Her heart is normal
- She has high-output failure
- She is in shock due to a non-cardiac cause

The right heart and wedge catheters show normal saturations, the latter suggesting that she has good pulmonary oxygenation and so these features would argue against any failure.

Decreased or high output failure would certainly argue against shock of any sort; therefore, one cannot go as far as to say that she has a normal heart, so the best response (by a process of elimination) is that she has a normal output.

Work Smart Session - MRCP Part 1

Time taken: 9 mins 29 secs

Question: 6 of 100

You are reviewing the results of a clinical trial of a new agent for treating type 2 diabetes mellitus. There are a number of analyses presented as part of the study.

Which of the following would be considered the most robust?

(Please select 1 option)

○	All patients who took one dose of medication
○	Intention to treat ← This is the correct answer
○	One month completer
◉	Per protocol ✕ Incorrect answer selected
○	Trial completer

The intention to treat (ITT) analysis contains all the patients randomised to a particular therapy regardless of whether they received it or not. ITT is considered to be the analysis which is least subject to bias.

Completer analyses, whether they took one dose of medication, one month of medication or completed the study, are subject to degrees of bias.

A per protocol analysis may exclude patients who suffered an event but then did not follow the protocol accurately, for example, a patient treated with the diabetes agent who was admitted to hospital, but missed one to two doses of medication.

A 60-year-old man was diagnosed last year with adenocarcinoma of the lung and a 4 cm mass lesion was treated with a right lower lobectomy.

He now has an abdominal CT scan that reveals scattered hepatic mass lesions and hilar lymphadenopathy. For several weeks, he has had increasing malaise.

His results show

Urinalysis	Protein +++
24 hour urine protein	2.7 g/24hr
Serum urea	30 mmol/L (2.5-7.5)
Serum creatinine	450 µmol/L (60-110)

A renal biopsy shows focal deposition of IgG and C3 with a granular pattern.

What is the most likely diagnosis?

(Please select 1 option)

- Goodpasture's syndrome
- Membranous glomerulonephritis
- Minimal change glomerulonephritis
- Nodular glomerulosclerosis
- Rapidly progressive glomerulonephritis

A 15-year-old girl was seen by her family physician because of increasing lethargy. She had a recent history of the "flu".

Biochemistry tests show that she has renal impairement.

Serum sodium	140 mmol/L (137-144)
Serum potassium	4.2 mmol/L (3.5-4.9)
Serum urea	28 mmol/L (2.5-7.5)
Serum creatinine	280 µmol/L (60-110)

Her condition does not improve after several weeks on corticosteroid therapy, so a renal biopsy is performed. The biopsy demonstrates the presence of segmental sclerosis of 3 of 10 glomeruli identified in the biopsy specimen.

Immunofluorescence studies and electron microscopy do not reveal evidence for immune deposits.

What is the most appropriate advice to give regarding her condition?

(Please select 1 option)

- She has an underlying malignancy
- She may require a renal transplant in 10 years
- She will improve if she loses weight
- She will likely develop a restrictive lung disease
- She will probably improve with additional corticosteroid therapy

Done

Serum urea	28 mmol/L (2.5-7.5)
Serum creatinine	280 µmol/L (60-110)

Her condition does not improve after several weeks on corticosteroid therapy, so a renal biopsy is performed. The biopsy demonstrates the presence of segmental sclerosis of 3 of 10 glomeruli identified in the biopsy specimen.

Immunofluorescence studies and electron microscopy do not reveal evidence for immune deposits.

What is the most appropriate advice to give regarding her condition?

(Please select 1 option)

- She has an underlying malignancy
- **She may require a renal transplant in 10 years** ✓ Correct
- She will improve if she loses weight
- She will likely develop a restrictive lung disease
- She will probably improve with additional corticosteroid therapy

The findings point to focal segmental glomerulosclerosis (FSGS) which leads to chronic renal failure in half of cases.

The lack of resolution with corticosteroid therapy and the progression to chronic renal failure is what sets FSGS apart from minimal change disease.

Question: 73 of 100

A 44-year-old man has had no major medical problems throughout his life, except for arthritis pain involving all extremities for the past couple of years.

He has had worsening orthopnoea and ankle oedema in the past six months. He is afebrile. There is no chest pain. A chest x ray shows cardiomegaly with both enlarged left and right heart borders, along with pulmonary oedema.

Laboratory test findings include:

Sodium	139 mmol/l	(137-144)
Potassium	4.3 mmol/l	(3.5-4.9)
Urea	7 mmol/l	(2.5-7.5)
Creatinine	95 µmol/l	(60-110)
Glucose	8.6 mmol/l	(3.0-6.0)

Which of the following additional laboratory test findings is he most likely to have?

(Please select 1 option)

- Anti-centromere antibody titre of 1:320
- Erythrocyte sedimentation rate of 79 mm/hr
- Haemoglobin of 10.7 g/dl with MCV of 72 fl
- Serum ferritin of 3400 pmol/l
- Spherocytes in his peripheral blood smear

Which of the following additional laboratory test findings is he most likely to have?

(Please select 1 option)

○	Anti-centromere antibody titre of 1:320
○	Erythrocyte sedimentation rate of 79 mm/hr
○	Haemoglobin of 10.7 g/dl with MCV of 72 fl
◉	Serum ferritin of 3400 pmol/l ✓ Correct
○	Spherocytes in his peripheral blood smear

He has findings of a cardiomyopathy with right and left heart failure. Hereditary haemochromatosis (HHC) is suspected with a serum ferritin greater than 1000 and confirmed by genetic testing.

Hereditary haemochromatosis is characterised by diabetes, congestive cardiac failure (CCF), pseudogout and slate-grey skin.

"HHC is an autosomal recessive condition and in 90% of cases in the United Kingdom (UK) the condition is owing to homozygosity for the C282Y mutation in the HFE gene. A second mutation in the HFE gene, H63D, can cause the disease when in the presence of a single C282Y mutation (the so-called 'compound heterozygote' state). These mutations are common in people of Northern European origin with a carrier frequency of the C282Y mutation of one in 10-17, in the UK, suggesting a prevalence of people homozygous for the C282Y mutation of between one in 100 and one in 280.

"If HHC becomes symptomatic by mid-life, a general practitioner (GP) with a list size of 2,000 patients should have approximately four cases. In our experience most GPs claim to have never seen a case. Herein lies the conundrum: is HHC far more common than is currently recorded in clinical records and death registers because it is not being diagnosed, or does significant disease not develop in a large proportion of C282Y homozygotes and compound heterozygotes?"

Further reading:
Hereditary haemochromatosis: never seen a case? (pdf) Br J Gen Pract. 2001 May; 51(466): 347-348.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 39 mins 35 secs

Question: 74 of 100

Which of the following is found in subjects acclimatised to life at high altitudes?

(Please select 1 option)

◉	Increased mean corpuscular haemoglobin concentration ✗ Incorrect answer selected
○	Increased pulmonary artery pressure ← This is the correct answer
○	Periodic respiration
○	Reduced airway resistance
○	Reduced cardiac output

Discriminating question!

Acclimatisation results in increased Hb with erythrocytosis.

Periodic respiration is a feature of non-acclimatisation.

Respiration is normal when subjects are acclimatised to altitude as is cardiac output.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 39 mins 35 secs

Question: 75 of 100

Which of the following statements is true of Xenotransplantation?

(Please select 1 option)

- Has not yet been performed in humans
- Is characterised by a vigorous early cell-mediated immune response
- Is the transfer of organs between species
- Is the transfer of tissue grown in-vitro
- Requires a close HLA match

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 40 mins 43 secs

Question: 75 of 100

Which of the following statements is true of Xenotransplantation?

(Please select 1 option)

- Has not yet been performed in humans
- Is characterised by a vigorous early cell-mediated immune response
- Is the transfer of organs between species ✓ Correct
- Is the transfer of tissue grown in-vitro
- Requires a close HLA match

Xenotransplantation is the transfer of organs between species - particularly the transfer of animal organs to humans. Compare this with allotransplantation which is the transfer of organs within the same species.

There have already been several documented cases of xenotransplantation - baboon heart, chimpanzee kidneys.

A close human leukocyte antigen (HLA) match is not possible of course, unless a transgenic species is used that express human major histocompatability complexes (HLA).

Early immune response is humoral - immunoglobulin M (IgM).

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 40 mins 43 secs

Question: 76 of 100

Adequate randomisation can be assumed in which of the following circumstances?

(Please select 1 option)

- All consecutive patients attending a tertiary referral centre
- A sample based on a family cluster
- A sample of those judged to be appropriate for inclusion in the study
- A sample using healthy volunteers
- A stratified random sample

A stratified random sample ← This is the correct answer

The actual patients included in the study often differ substantially from what was initially intended. This dramatically alters one's interpretation of a study.

The target population includes all those with a given disease, and is seldom fully accessible. The accessible population available for study may be biased in time or place.

It is important to randomise when selecting a sample which is supposed to represent the target population. In simple randomisation, every member of the population is numbered, and a random sample is selected.

In a stratified random sample, groups of interest are identified, and then randomisation occurs within those groups.

In systematic sampling a "periodic" approach is used. This is not really random and is open to alteration and bias.

In a cluster sample, a natural grouping of population is used (such as a family), but this may well be unrepresentative of the whole population.

Classic errors in randomisation are:

- Consecutive sampling, which may well not be representative if the study time is short.
- Convenience sampling: strong potential for bias, with volunteers generally healthier than others.
- Judgmental sample: including those that you want only. The potential for systematic error is enormous.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 41 mins 40 secs

Question: 77 of 100

Which of the following conditions is most likely to be detectable by growth monitoring?

(Please select 1 option)

- Hyperthyroidism
- Hypothyroidism
- Insulin dependent diabetes mellitus
- Pseudohypoparathyroidism
- XYY syndrome

Submit answer | Skip question | Tag Question | Remove question

Page Safety Tools

(Please select 1 option)

○	Hyperthyroidism
○	Hypothyroidism ← This is the correct answer
○	Insulin dependent diabetes mellitus
○	Pseudohypoparathyroidism
◉	XYY syndrome ✕ Incorrect answer selected

Benefits of growth monitoring include:

Early detection of conditions such as:

- Hypothyroidism
- Growth hormone insufficiency
- Syndromes: Turner, Russell-Silver, Noonan's, skeletal dysplasias
- Growth impairment, for example, coeliac disease, inflammatory bowel disease or chronic renal failure
- Intracranial tumours
- Short normal children
- Children with short stature
- Health promotion: impaired growth may be associated with child abuse or neglect for example
- Focus of interest for parents.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 43 mins 30 secs

Question: 78 of 100

Which of the following suggests a diagnosis of Hurler's syndrome rather than Hunter's syndrome?

(Please select 1 option)

◉	Cardiomyopathy ✕ Incorrect answer selected
○	Cloudy cornea ← This is the correct answer
○	Mental retardation
○	Skeletal abnormalities
○	X linked inheritance

Hunter's syndrome (MPS-2) is of X linked inheritance. The corneas are clear. The skeletal involvement tends to be mild with no gibbous present, though scoliosis is often found.

Mental retardation and heart involvement are less severe than in Hurler's syndrome.

Hurler's syndrome (MPS-1) is autosomal recessive in inheritance and is associated with cloudy cornea. There is severe mental retardation, and gibbous deformation of the spine is characteristic. There is the characteristic coarse facies with hepatosplenomegaly.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 44 mins 8 secs

Question: 79 of 100

Which of the following micro-organisms is generally sensitive to benzylpenicillin?

(Please select 1 option)

- *Bordetella pertussis*
- *Cryptococcus neoformans*
- *Legionella pneumophila*
- *Mycoplasma pneumoniae*
- ◉ *Streptococcus Pneumonaie* ✓ Correct

Penicillin binds to specific penicillin-binding proteins (PBP's) in the cell wall, mainly of gram positive organisms.

Penicillin resistance is usually due to production of altered PBPs or beta-lactamases which leave the...

Penicillin is mainly useful for group A Strep., Group B Strep., meningococcal and pneumococcal infections, though anthrax are also sensitive.

Pneumococci with modified PBPs are an increasing problem.

A 62-year-old man who has recently had his medication for hypertension altered presents with flushing, stridor, shortness of breath and hypotension.

He comes to the emergency department and receives intravenous hydrocortisone, intramuscular adrenaline, and intravenous antihistamine. After a slow recovery he is discharged home for planned review at the allergy clinic.

Which of the following medications is most likely to be responsible for his presentation?

(Please select 1 option)

- Amlodipine
- Atenolol
- Bendroflumethiazide
- Doxazosin
- Ramipril ✓ Correct

This man has presented with anaphylaxis.

Whilst angio-oedema may be hereditary or idiopathic, it is also associated with use of both ACE inhibitors and angiotensin receptor blockers (ARB). Given that he has recently increased his anti-hypertensive medication, presentation with angio-oedema associated with ACE inhibitor therapy seems the most likely explanation.

He should cease ramipril therapy and not commence either ACE inhibitors or ARBs in the future.

Work Smart Session - MRCP Part 1

Time taken: 11 mins 22 secs

Question: 8 of 100

A 34-year-old man with polycystic kidney disease attends the transplant clinic with his 19-year-old brother.

His most recent creatinine has been measured at 342 µmol/l, and he is on several anti-hypertensive drugs and erythropoietin injections to maintain his haemoglobin, which was recently measured as 10.4 g/l.

On examination his BP is 149/87 mmHg. Other findings are consistent with chronic renal failure. His father had end stage renal failure for some years before his death.

Which of the following most accurately reflects the chances of his brother being able to donate a kidney to him?

(Please select 1 option)

- 0%

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 45 mins 8 secs

Question: 80 of 100

Metabolic alkalosis is characteristically found in which of the following?

(Please select 1 option)

- An infusion of sodium chloride
- Ileostomy
- Mineralocorticoid deficiency
- (●) Pyloric stenosis ✓ Correct
- Salicylate poisoning

Pyloric stenosis is associated with vomiting and the loss of stomach content - hence a metabolic alkalosis.

Normal saline has a pH of 5 and may produce a mild metabolic acidosis with significant infusions.

Ileostomy may be associated with a loss of bicarbonate ions and hence acidosis.

Mineralocorticoid excess (Conn's syndrome) is also associated with a metabolic alkalosis.

Salicylates are themselves acidic and produce a metabolic acidosis.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 46 mins 21 secs

Question: 81 of 100

Which of the following is true regarding chromosomes?

(Please select 1 option)

- Down syndrome is most commonly due to an extra copy of chromosome 21 inherited from the father
- A fetus with triploidy will have 47 chromosomes
- Heterochromatin is mostly composed of active genes
- **The normal human karyotype contains 22 pairs of autosomes** ✓ Correct
- Telomeres provide the point of attachment to the mitotic spindle

The human karyotype consists of 22 pairs of autosomes and 1 pair of sex chromosomes.

Down syndrome is most commonly due to trisomy of C21 with the majority a consequence of non-disjunction within the ovum.

Trisomy results in 47 chromosomes whereas triploidy is the presence of three complete sets of chromosomes instead of two in all cells.

Heterochromatin is of little genetic significance containing mostly inactivated genes.

Telomeres are the distal extremities of the chromosomal arms but the centromeres provide the point of attachment to the mitotic spindle.

Which of the following is a typical feature of farmer's lung?

(Please select 1 option)

○	Basal crackles ← This is the correct answer
○	Eosinophilia
○	Haemoptysis
○	Increased pCO2
◉	Positive serum paraproteins ✕ Incorrect answer selected

Farmer's lung is the commonest occupational extrinsic allergic alveolitis, due to thermophillic actinomycetes. Crackles are typically heard at the bases.

Eosinophilia can be seen but is not typical.

Immunoglobulin levels are frequently elevated but not a paraprotein.

P02 may be decreased particularly with exercise.

A restrictive pattern on LF studies is seen.

(Dr Shu Ho)

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 48 mins 21 secs

Question: 85 of 100

A study of the intellectually handicapped was performed.

The 112 subjects, put through program A showed an increase in their mean IQ score of 6 points.

The 115 subjects, put through program B showed an increase in their mean IQ score of 4.

The p value was >0.05 .

Which of the following is true?

(Please select 1 option)

- a. The numbers are too large for a Student t-test
- b. The study demonstrates the usefulness of program A
- c. The distribution of individual values is not important
- d. Even though the difference between the means is not significant it would be appropriate to calculate confidence intervals
- f. The above results would be found by chance in less than 1:20

The p value was >0.05 .

Which of the following is true?

(Please select 1 option)

○	a. The numbers are too large for a Student t-test
○	b. The study demonstrates the usefulness of program A
○	c. The distribution of individual values is not important
◉	d. Even though the difference between the means is not significant it would be appropriate to calculate confidence intervals ✓ Correct
○	f. The above results would be found by chance in less than 1:20

a. The t-test could be used in the comparison of data and the larger the sample size the more meaningful the data.

b. A is no more useful than B or even simply repeating an IQ test?

c+d. This gives us an idea of the distribution of the data. Confidence intervals may provide more meaningful data concerning the study.

e. The chances are greater than 1 in 20 as P is greater than 0.05.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 50 mins 40 secs

Question: 86 of 100

Which one of the following is true concerning antidiuretic hormone (ADH)?

(Please select 1 option)

- Carbamazepine potentiates its release
- Ethanol potentiates its release
- It circulates in the blood bound to neurohypophysin
- It is a cyclic octapeptide
- It is synthesised in the posterior pituitary

Question: 86 of 100

Which one of the following is true concerning antidiuretic hormone (ADH)?

(Please select 1 option)

○	Carbamazepine potentiates its release ← This is the correct answer
◉	Ethanol potentiates its release ✕ Incorrect answer selected
○	It circulates in the blood bound to neurohypophysin
○	It is a cyclic octapeptide
○	It is synthesised in the posterior pituitary

ADH is a nonapeptide manufactured in the paraventricular and supra-optic nuclei of the hypothalamus and released from the posterior pituitary.

It acts on the collecting ducts improving water permeability and hence water retention.

Carbamazepine as well as other agents such as thiazides and selective serotin reuptake inhibitors (SSRIs) may potentiate its release.

Ethanol usually inhibits release.

Question: 87 of 100

Which of the following is a feature of pseudohypoparathyroidism?

(Please select 1 option)

- Increased urinary phosphate and cAMP with PTH infusion
- Low serum calcium and high serum phosphate ✓ Correct
- Low serum calcium and low serum phosphate
- Low serum PTH
- Shortened second and third metacarpals

The biochemistry shows a hypocalcaemia with hyperphosphataemia being usual but elevated parathyroid hormone (PTH) due to resistance to PTH.

This is due to mutation of the PTH receptor with abnormality of the Gsalpha subunit with reduced cyclic adenosine monophosphate (cAMP) production following a PTH infusion.

There are associated phenotypic signs including short stature, low IQ and shortened fourth and fifth metacarpals.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 53 mins 13 secs

Question: 88 of 100

An Afro-Carribean male aged 48 years presents with gradual onset of exertional dyspnoea, non-productive cough, malaise, weight loss and polyarthralgia.

Schirmer's test indicates a dry eye. x Ray of the hand shows punched out osteopenic lesions.

Which of the following investigations is unlikely to be helpful in establishing the diagnosis of this condition?

(Please select 1 option)

- Quantitative immunoglobulins.
- Serum calcium
- Serum phosphorus
- Thallium scan
- Urea and electrolytes

Schirmer's test indicates a dry eye. x Ray of the hand shows punched out osteopenic lesions.

Which of the following investigations is unlikely to be helpful in establishing the diagnosis of this condition?

(Please select 1 option)

○	Quantitative immunoglobulins.
○	Serum calcium
○	Serum phosphorus
◉	Thallium scan ✓ Correct
○	Urea and electrolytes

This condition is sarcoidosis. Serum calcium, serum phosphorus, chem7 and chem 20 and quantitative immunoglobulins are all used in establishing the diagnosis. Gallium scan is helpful in sarcoidosis. (Radiology of extrathoracic sarcoid ...)

Gallium scan vs. Thallium scan.

Gallium scan (radioactive ^{67}Ga) is used to detect inflammation - such as in inflammatory disorders or malignancy.

Thallium (radioactive ^{201}Tl) is a potassium analogue and is used to demonstrate areas of poor perfusion. It is particularly used in cardiology to detect areas of ischaemia.

Question: 89 of 100

Gaucher's disease is associated with the deficiency of:

(Please select 1 option)

○	Arylsulphatase-A
◉	B- Glucosidase ✓ Correct
○	Hexosaminidase A
○	Iduronidase
○	Sphingomyelinase

Hexosaminidase A deficiency is associated with Tay-Sachs disease.

Sphingomyelinase deficiency is associated with Niemann-Pick disease.

Arylsulphatase-A deficiency is associated with metachromic leucodystrophy.

Iduronidase deficiency is associated with Hurler's syndrome.

A 34-year-old man with polycystic kidney disease attends the transplant clinic with his 19-year-old brother.

His most recent creatinine has been measured at 342 µmol/l, and he is on several anti-hypertensive drugs and erythropoietin injections to maintain his haemoglobin, which was recently measured as 10.4 g/l.

On examination his BP is 149/87 mmHg. Other findings are consistent with chronic renal failure. His father had end stage renal failure for some years before his death.

Which of the following most accurately reflects the chances of his brother being able to donate a kidney to him?

(Please select 1 option)

◉	0% ✕ Incorrect answer selected
○	25%
○	33%
○	50% ← This is the correct answer
○	100%

Polycystic kidney disease (PCKD) carries an autosomal dominant inheritance pattern. As such, with one affected parent, each child has a 50% chance of inheriting the PCKD gene.

Whilst ultrasound is very sensitive in detection of PCKD in patients over 20, in those under 20 it is not 100% accurate.

It may not seem immediately obvious to consider a family member as a potential donor, but they may be a valuable source for a kidney in this situation.

(Please select 1 option)

○	Are formed from the cyclo-oxygenase pathway
○	Are synthesised by fibroblasts
○	Decrease vascular permeability
○	Leukotriene D4 has been identified as SRS-A which causes bronchial wall smooth muscle relaxation
◉	Stimulate mucus secretion ✓ Correct

Leukotrienes are synthesised by leucocytes.

They are mediators of allergic reaction.

They increase vascular permeability and attract neutrophils and eosinophils to inflammatory sites.

Leukotrienes are synthesised via the lipoxygenase pathway.

Leukotriene D4 has been identified as SRS-A which causes bronchial wall and intestinal smooth muscle contraction (not dilatation).

Leukotrienes also stimulate mucus production, an important consideration in the pathophysiology of bronchial asthma.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 6 mins 51 secs

Question: 91 of 100

Restriction enzymes:

(Please select 1 option)

- Are involved in cell cycle arrest
- Cut DNA ← This is the correct answer
- Degrade DNA
- Join two pieces of DNA together
- Synthesise DNA ✕ Incorrect answer selected

Restriction enzymes cut deoxyribonucleic acid (DNA) at sequences specific for each restriction enzyme; they are vital tools for molecular biology and molecular genetic research.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 7 mins 49 secs

Question: 92 of 100

Which of the following is a glycoprotein hormone?

(Please select 1 option)

- Cortisol
- Growth hormone releasing hormone
- Oxytocin
- Thyrotropin (TSH) ✓ Correct
- Thyrotropin releasing hormone (TRH)

Thyrotropin is glycosylated, cortisol is a steroid hormone and the others are peptide hormones/neuropeptides which as a group are rarely glycosylated.

Question: 93 of 100

Which of the following would be most in keeping with a diagnosis of polymyalgia rheumatica (PMR)?

(Please select 1 option)

○	Erythema nodosum
○	Increased alkaline phosphatase ← This is the correct answer
○	Raised creatine kinase (CK)
◉	Shoulder and pelvic girdle pain in a 40-year-old man ✕ Incorrect answer selected
○	Sudden loss of vision in one eye

Liver enzymes are elevated in most patients.

Visual disturbances are suggestive of temporal arteritis not PMR, and are due to ischaemic changes in ciliary arteries (optic neuritis/infarction) and less commonly due to central artery occlusion.

Raised CK occurs in polymyositis.

PMR is rare before the age of 50 years.

Shop

(Please select 1 option)

○	Autosomal dominant
○	Autosomal recessive
○	Mitochondrial
◉	X-linked dominant ✓ Correct
○	X-linked recessive

This is a tricky question and the crucial part is recognising that X-linked dominant conditions are transmitted by a father to all his daughters and that, on balance, this is a better explanation of the genetics than the tenuous assertion that an autosomal dominant condition has by chance affected three daughters but neither of two sons.

X-linked dominant disorders are rare (for example, vitamin D-resistant rickets). They affect both sexes but females more than males.

All children of a homozygous mother are affected.

Half the sons and half the daughters inherit the disorder from an affected mother with the trait.

An affected father passes the disease to all his daughters but none of his sons - as in this example.

Question: 97 of 100

Apoptosis is the process of programmed cell death and occurs in cells that have damaged DNA.

A mediator of this process is a tumour suppressor gene that inhibits mitosis and promotes apoptosis.

This gene is which of the following?

(Please select 1 option)

○	BCL-2
○	Caspases
○	Fas (CD95)
◉	p53 ✓ Correct
○	Ras

BCL-2 is an inhibitor of apoptosis.

Fas is a cell receptor and caspases are present in all cells; both promote apoptosis but are not tumour suppressor genes.

Ras is an oncogene.

◉	A small viral particle ✕ Incorrect answer selected
○	Bacterial DNA separate from the chromosome ← This is the correct answer
○	Consisting of multiple copies of a single gene
○	Having multiple origins of replication

Plasmids are circular molecules of bacterial deoxyribonucleic acid (DNA) separate from the bacterial chromosome.

They are usually:

- small

- consisting of a few thousand base pairs

- carry one or a few genes, and

- have a single origin of replication.

Genes on plasmids with multiple copies are usually expressed at higher levels.

In nature these genes often encode for proteins such as those needed for bacterial resistance.

Plasmids can be used to clone genes by splicing a particular gene into a plasmid and then allowing the bacteria to multiply - this is then called recombinant plasmid DNA.

Question: 99 of 100

Transcription RNA (tRNA) has three bases specific for a particular amino acid with which it binds to messenger RNA (mRNA).

Which of the following is this specific area of tRNA?

(Please select 1 option)

○	Anticodon ← This is the correct answer
◉	Codon ✕ Incorrect answer selected
○	Exon
○	Intron
○	Transposon

mRNA has codons which are bound by the anticodons on tRNA during translation of protein synthesis.

Exons are coding sequences in the mRNA and introns are areas of unknown function.

Transposons are genetic sequences that have been transposed from one part of DNA to another.

Work Smart Session - MRCP Part 1

Time taken: 15 mins 29 secs

Question: 9 of 100

Which of the following arteries are branches of the axillary artery?

(Please select 1 option)

- Inferior ulnar collateral artery
- Internal thoracic artery
- Profunda brachi artery
- Subscapular artery ✓ Correct
- Superior ulnar collateral artery

The internal thoracic artery arises from the subclavian artery.

The inferior and superior ulnar collateral arteries and the profunda brachii are branches of the brachial artery.

The subscapular artery arises from the axillary and is its largest branch, eventually anastomosing with the lateral thoracic and intercostal arteries.

Work Smart Session - MRCP Part 1

Time taken:

Question: 1 of 82

A 17-year-old man comes to the clinic. He has recently returned from a holiday to Spain with his friends and is very disappointed with the quality of his tan, as there appear to be large depigmented areas on the skin of his abdomen and on his back. He says the areas are itchy.

On examination you confirm the depigmentation, and there is superficial scaling over the areas.

Which of the following is the most appropriate treatment?

(Please select 1 option)

- Oral antifungals
- Oral corticosteroids
- Reassurance
- Topical antifungals
- Topical corticosteroids

Work Smart Session - MRCP Part 1

Time taken: 21 mins 38 secs

Question: 10 of 82

Which of the following is true regarding diabetic foot ulceration?

(Please select 1 option)

- Autonomic neuropathy results in increased resting blood flow
- Callus formation at pressure areas is an important predictor of ulceration
- Plantar ulceration is most commonly due to atherosclerosis
- Skin infection is the most common initiating event in ulceration
- Radiography can readily distinguish between Charcot's joint and osteomyelitis

Work Smart Session - MRCP Part 1

Time taken: 33 mins 29 secs

Question: 10 of 82

Which of the following is true regarding diabetic foot ulceration?

(Please select 1 option)

○	Autonomic neuropathy results in increased resting blood flow
○	Callus formation at pressure areas is an important predictor of ulceration ← This is the correct answer
○	Plantar ulceration is most commonly due to atherosclerosis
◉	Skin infection is the most common initiating event in ulceration ✕ Incorrect answer selected
○	Radiography can readily distinguish between Charcot's joint and osteomyelitis

Callus formation at pressure areas is an important predictor of potential ulceration.

Plantar ulceration is usually a consequence of neuropathy.

Minor skin trauma is probably the most common initiating event.

Blood flow is often decreased with autonomic neuropathy hence sympathectomy may be performed to improve skin blood flow.

It is difficult to distinguish radiographically between Charcot's joint and osteomyelitis.

Work Smart Session - MRCP Part 1

Time taken: 34 mins 8 secs

Question: 11 of 82

Which of the following determines the primary mechanical properties of skin?

(Please select 1 option)

- Dermis
- Stratum basale
- Stratum corneum ✓ Correct
- Stratum granulosum
- Subcutaneous tissue

The stratum corneum is the last layer and provides a mechanical barrier to the skin and therefore determines the mechanical functions of the skin. The hands and feet have thick stratum corneum as compared to the lips and eyelids. The thicker the stratum corneum is the more protection there is for the skin.

The dermis also has some factor to play with its elastic fibres and fibrous tissue.

The rest of the layers are also important but the mechanical properties are primarily determined by the stratum corneum.

Work Smart Session - MRCP Part 1

Time taken: 34 mins 8 secs

Question: 12 of 82

A 43-year-old female presents with a weepy, erythematous rash mainly affecting the forehead, scalp, neck and upper back.

Three days earlier she had used red hair dye at home to self-administer 'highlights'.

What is the likely diagnosis?

(Please select 1 option)

- Acne rosacea
- Contact allergic dermatitis
- Eczema
- Psoriasis
- Seborrhoeic dermatitis

What is the likely diagnosis?

(Please select 1 option)

○	Acne rosacea
◉	Contact allergic dermatitis ✓ Correct
○	Eczema
○	Psoriasis
○	Seborrhoeic dermatitis

Hair dye contains substances which may induce contact allergic dermatitis.

This type of reaction is typical for this sort of time scale, and is an example of a type IV, or delayed, hypersensitivity reaction.

Sensitisation occurs on initial exposure to the allergen and 'memory' T-cells proliferate in lymphoid tissue. Subsequent exposure to allergen induces activation of the T-lymphocytes and an inflammatory response.

Hairdressing chemicals are a very common cause of contact allergic dermatitis, a disorder which is very common amongst the hairdressing community.

A lady at this age is unlikely to present with a new, previously undiagnosed case of eczema.

Acne rosacea is usually a disorder of the skin on the cheeks and nose.

Work Smart Session - MRCP Part 1

Time taken: 36 mins 33 secs

Question: 13 of 82

During a follow-up visit at an asthma clinic a 38-year-old female complains of the appearance of a mole.

Which of the following characteristics of the lesion would raise suspicion that it is a malignant melanoma?

(Please select 1 option)

- Lesion has irregular outline
- Lesion is deeply pigmented
- Lesion is present on face
- Lesion is raised
- Lesion is 6 mm in diameter

During a follow-up visit at an asthma clinic a 38-year-old female complains of the appearance of a mole.

Which of the following characteristics of the lesion would raise suspicion that it is a malignant melanoma?

(Please select 1 option)

◉	Lesion has irregular outline ✓ Correct
○	Lesion is deeply pigmented
○	Lesion is present on face
○	Lesion is raised
○	Lesion is 6 mm in diameter

The mnemonic of ABCDE regarding characteristics of a melanoma are as follows:

- A - Asymmetry - one half of the lesion does not match the other half
- B - Border irregularity
- C - Colour variegation - pigmentation is not uniform
- D - Diameter- a diameter 7 mm warrants investigation although changes in size are also important
- E - Evolution - evolving size or changes in characteristics such as nodules.

Work Smart Session - MRCP Part 1

Time taken: 37 mins 48 secs

Question: 14 of 82

A 47-year-old woman presented with a history several years of dysphagia, hard calcified nodules in the fingers, and cold hands. Examination revealed calcified nodules, sclerodactyly and facial telangiectasia.

Which one of the following antibodies is most likely to be found in the blood?

(Please select 1 option)

- Anticardiolipin
- Anticentromere
- Anti-DNA antibodies
- Antimitochondrial
- Antimyeloperoxidase

(Please select 1 option)

○	Anticardiolipin
◉	Anticentromere ✓ Correct
○	Anti-DNA antibodies
○	Antimitochondrial
○	Antimyeloperoxidase

This patient has CREST syndrome which consists of

Calcinosis

Raynaud's phenomenon

(o)**E**sophageal dysmotility

Sclerodactyly

Telangiectasia.

It is a limited form of scleroderma with less involvement of internal organs and is better referred to as 'cutaneous limited systemic sclerosis'.

Work Smart Session - MRCP Part 1

Time taken: 41 mins 9 secs

Question: 15 of 82

A 59-year-old patient of South Asian origin presents with a widespread blistering rash.

Which of the following features would be consistent with a diagnosis of pemphigus?

(Please select 1 option)

- Acanthosis
- Blisters arising within the subepidermal area
- IgA antibodies
- Oral involvement
- Treatment with methotrexate

Question: 15 of 82

A 59-year-old patient of South Asian origin presents with a widespread blistering rash.

Which of the following features would be consistent with a diagnosis of pemphigus?

(Please select 1 option)

○	Acanthosis
○	Blisters arising within the subepidermal area
○	IgA antibodies
◉	Oral involvement ✓ Correct
○	Treatment with methotrexate

Pemphigus is associated with loss of intercellular cohesion in the lower part of the epidermis, leading to acantholysis (separation of keratinocytes). Pemphigus is classically associated with flaccid blistering, and often with immunoglobulin (Ig)G antibodies.

Treatment may be successful with azathioprine.

Pemphigoid is associated with subepidermal bullae.

Work Smart Session - MRCP Part 1

Time taken: 56 mins 52 secs

Question: 17 of 82

A 16-year-old boy presents with scaly patches on his scalp. Examination reveals well-circumscribed, circular areas of hair loss, 2-5 cm in diameter with scaling and raised margins. There is no scarring.

What is the most likely cause in this patient?

(Please select 1 option)

- Discoid lupus erythematosus
- Lichen planus
- Morphoea
- Systemic lupus erythematosus
- Tinea capitis

Tools

○	Morphoea
○	Systemic lupus erythematosus
◉	Tinea capitis ✓ Correct

This patient has non-scarring alopecia due to invasion of hairs by dermatophytes, most commonly *Trichophyton tonsurans*.

The most common causes of non-scarring alopecia include:

- Telogen effluvium
- Androgenetic alopecia
- Alopecia areata
- Tinea capitis
- Traumatic alopecia.

Less commonly, non-scarring alopecia is associated with lupus erythematosus and secondary syphilis.

Scarring alopecia is more frequently the result of a primary cutaneous disorder such as:

- Lichen planus
- Folliculitis decalvans
- Cutaneous lupus
- Linear scleroderma (morphoea).

Work Smart Session - MRCP Part 1

Time taken: 58 mins 33 secs

Question: 18 of 82

A 22-year-old man consults his GP complaining of redness and itching on his face and hands.

He has regularly visited another GP for similar complaints within the last two years and has been signed off on sick leave from employment as a builder. He is in receipt of benefits and reports that he is in the process of making an insurance claim for loss of earnings.

He says that there was one ointment that cured the problem but he had not been able to find any proprietary medication that works. Examination showed no skin lesions and no apparent rash.

What is the most likely diagnosis?

(Please select 1 option)

- Conversion disorder
- Delusional disorder
- Malingering
- Munchausen syndrome
- Obsessive compulsive disorder

Submit answer | Skip question | Tag Question | Remove question

builder. He is in receipt of benefits and reports that he is in the process of making an insurance claim for loss of earnings.

He says that there was one ointment that cured the problem but he had not been able to find any proprietary medication that works. Examination showed no skin lesions and no apparent rash.

What is the most likely diagnosis?

(Please select 1 option)

- Conversion disorder
- Delusional disorder
- Malingering ✓ Correct
- Munchausen syndrome
- Obsessive compulsive disorder

In somatoform disorders, both illness production and motivation are unconscious drives.

In malingering, as suggested here, the patient consciously fakes or claims to have a disorder in order to attain a specific gain (for example, financial).

Münchausen syndrome is manifested by a chronic history of multiple hospital admissions and willingness to receive invasive procedures.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 6 mins 37 secs

Question: 19 of 82

A 45-year-old teacher presents six weeks after he returns from a hiking holiday in South America with a shallow, painless ulcer of the nose.

What is the likely diagnosis?

(Please select 1 option)

- *Fusobacterium ulcerans*
- Leishmaniasis ✓ Correct
- Squamous cell carcinoma
- Trichomoniasis
- Trypanosomiasis

The likely diagnosis, given the history, is cutaneous leishmaniasis. Lesion pain and pruritis may be present in cutaneous leishmaniasis, but are not typical.

Diagnosis is by histologic section with staining for amastigotes. *Leishmania braziliensis* is the likely pathogen which is spread by sandfly bites in endemic areas.

Fusobacteria cause the tropical ulcer, an intensely painful, shallow ulcer.

Work Smart Session - MRCP Part 1

Time taken: 2 mins 16 secs

Question: 1 of 82

A 17-year-old man comes to the clinic. He has recently returned from a holiday to Spain with his friends and is very disappointed with the quality of his tan, as there appear to be large depigmented areas on the skin of his abdomen and on his back. He says the areas are itchy.

On examination you confirm the depigmentation, and there is superficial scaling over the areas.

Which of the following is the most appropriate treatment?

(Please select 1 option)

- Oral antifungals
- Oral corticosteroids
- Reassurance
- Topical antifungals ✓ Correct
- Topical corticosteroids

This patient has clinical findings which are typical of those seen in pityriasis versicolor, caused by a fungus known as *Malassezia furfur*. This causes more of a problem in hot weather, is present on the skin of the trunk, and leads to the depigmentation seen here.

Topical antifungals are the treatment of choice; if the depigmentation is extensive, a systemic compound like fluconazole may be used.

What is the most appropriate treatment?

(Please select 1 option)

○	Oral fluconazole
◉	Oral terbinafine ✓ Correct
○	Topical benzoic acid
○	Topical fluconazole
○	Topical terbinafine

This young woman has typical features of fungal nail infection - onychomycosis - and the most appropriate treatment is oral antifungals as topical antifungals may be effective for one or two nails but not where there are a number affected.

Further reading:
Guidelines for treatment of onychomycosis (pdf) British Journal of Dermatology 2003; 148: 402-410.

A 40-year-old female presents with a long history of excessive localised armpit sweating. She finds the problem embarrassing and has problems staining clothes. She has tried antiperspirants without relief.

Which is the most appropriate treatment that you would offer this patient?

(Please select 1 option)

- Amitriptyline
- Axillary surgery
- Botulinum toxin injection ✓ Correct
- Propantheline
- Topical aluminium salts

This woman has primary hyperhidrosis which can be quite psychologically disabling.

In this case the most appropriate treatment would be botulinum toxin injection to each axilla. This treatment is licensed for use and would be the preferred treatment before aluminium salts, as antiperspirants have failed.

Similarly, antimuscarinics are associated with systemic side effects that may prove intolerable and their efficacy is really not proven.

Pharmacological approaches should be tried before surgery.

- Erythema marginatum
- Erythema nodosum
- Livedo reticularis ✓ Correct
- Pyoderma gangrenosum

Livedo reticularis is due to dilation of capillary blood vessels and stagnation of blood within these vessels, producing a mottled discolouration of the skin.

It is described as being reticular (net-like), cyanotic, cutaneous discolouration surrounding pale central areas. It occurs mostly on the legs, arms and trunk and is more pronounced in cold weather.

Mostly it is idiopathic, or secondary to:

- malignancy
- vasculitis
- SLE
- cancer
- cholesterol embolisation.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 10 mins 9 secs

Question: 23 of 82

An 82-year-old lady had a history of a red facial rash and has suffered with venous eczema of the legs. She was treated for acne rosacea.

On examination, she was noted to have blue-grey discolouration of both legs.

What drug is most likely to have caused this?

(Please select 1 option)

- Amiodarone
- Ciprofloxacin
- Doxycycline
- Minocycline
- Oxytetracycline

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 11 mins 26 secs

Question: 23 of 82

An 82-year-old lady had a history of a red facial rash and has suffered with venous eczema of the legs. She was treated for acne rosacea.

On examination, she was noted to have blue-grey discolouration of both legs.

What drug is most likely to have caused this?

(Please select 1 option)

- Amiodarone
- Ciprofloxacin
- Doxycycline
- Minocycline ✓ Correct
- Oxytetracycline

This patient has developed skin pigmentation in her venous eczema due to treatment of her acne rosacea.

Tetracyclines are the most appropriate treatment of acne rosacea and the most likely of these to cause this bluish grey skin pigmentation in the legs is minocycline.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 11 mins 26 secs

Question: 24 of 82

A 22-year-old female presents with a six month history of increasing fatigue and arthralgia of the wrists and ankles. More recently, she has also noted a symmetrical rash on her cheeks and some hair loss.

What is the most likely diagnosis?

(Please select 1 option)

- Dermatomyositis
- Hypothyroidism
- Porphyria cutanea tarda
- Scleroderma
- Systemic lupus erythematosus (SLE)

(Please select 1 option)

○	Dermatomyositis
○	Hypothyroidism
○	Porphyria cutanea tarda
○	Scleroderma
◉	Systemic lupus erythematosus (SLE) ✓ Correct

This woman has clinical features consistent with systemic lupus erythematosus. She gives a history of fatigue which occurs in almost all SLE patients. Arthralgia and arthritis are the most common presenting manifestations of SLE typically affecting the small joints of the hands, wrists and knees. The symmetrical rash is the classical butterfly rash that occurs in a malar distribution. Alopecia is common and may be diffuse or patchy.

In dermatomyositis there is proximal, symmetrical muscle weakness that progresses over weeks to months. The typical lilac papular rash occurs over the dorsum of the metacarpophalangeal (Gottron's papules), elbows and knees.

Hypothyroidism does not result in a symmetrical facial rash.

The initial symptoms of scleroderma tend to be non-specific and may consist of fatigue, weakness and musculoskeletal complaints. Raynaud's phenomenon is an early symptom. Skin changes include telangiectasia, hyper- and hypo-pigmentation.

Sarcoidosis can present acutely with arthritis and erythema nodosum.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 13 mins 6 secs

Question: 25 of 82

A 31-year-old female presents with red scaly plaques on her cheeks, forehead and sides of the neck. On close inspection of the lesions there was plugging of some hair follicles with keratin and atrophy of the skin.

What is the most likely diagnosis?

(Please select 1 option)

- Atopic eczema
- Discoid lupus erythematosus
- Polymorphic light eruption
- Porphyria cutanea tarda
- Psoriasis

Tools

(Please select 1 option)

○	Atopic eczema
○	Discoid lupus erythematosus ← This is the correct answer
○	Polymorphic light eruption
○	Porphyria cutanea tarda
◉	Psoriasis ✕ Incorrect answer selected

This woman has discoid lupus erythematosus.

Lesions are discrete plaques, often erythematous, covered by scales that extend into dilated hair follicles. These lesions most typically occur on the face, scalp, in the pinnae, behind the ears and on the neck. They can exist in areas not exposed to the sun.

The lesions can progress, with active indurated erythema at the periphery. Central atrophic scarring is characteristic.

Amiodarone phototoxicity results in blue-grey skin pigmentation in sun-exposed areas.

In eczema dryness and lichenification are predominant features.

Psoriasis commonly appears as inflamed lesions covered with a silvery white scale.

Polymorphic light eruption is characterised by recurrent, abnormal, delayed reactions to sunlight, ranging from erythematous papules, papulovesicles, and plaques to erythema multiforme-like lesions on sunlight-exposed surfaces.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 15 mins 27 secs

Question: 26 of 82

A 22-year-old female is referred with symmetrical, depigmented areas on the arms and legs but has been otherwise quite well.

Which one of the following diseases is most likely to be associated with her skin disease?

(Please select 1 option)

- Diabetes mellitus
- Hypoparathyroidism
- Pernicious anaemia ✓ Correct
- Scleroderma
- Systemic lupus erythematosus (SLE)

She has vitiligo and consequently is 15 times more likely to be suffering from an additional autoimmune condition. Although hypoparathyroidism may be an associated autoimmune condition, pernicious anaemia occurs more frequently.

Vitiligo may be a component of the polyglandular autoimmune syndrome which includes type 1 diabetes, autoimmune adrenal insufficiency and autoimmune thyroid disease.

SLE causes post-inflammatory hypopigmentation and scleroderma is not associated.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 15 mins 27 secs

Question: 27 of 82

A 17-year-old pregnant female attends antenatal clinic and is noted to have scattered small, raised lesions on her trunk and axillary freckles.

She was not aware of any of her family members having these lesions.

What is the likely mode of inheritance of this condition?

(Please select 1 option)

- Autosomal dominant
- Autosomal recessive
- Trinucleotide repeating
- X-linked dominant
- X-linked recessive

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 17 mins 3 secs

Question: 27 of 82

A 17-year-old pregnant female attends antenatal clinic and is noted to have scattered small, raised lesions on her trunk and axillary freckles.

She was not aware of any of her family members having these lesions.

What is the likely mode of inheritance of this condition?

(Please select 1 option)

◉	Autosomal dominant ✓ Correct
○	Autosomal recessive
○	Trinucleotide repeating
○	X-linked dominant
○	X-linked recessive

This patient has neurofibromatosis with axillary freckling and neurofibromas.

This is usually inherited as autosomal dominant, although it may arise from a sporadic new mutation of the NF1 gene.

A 22-year-old female returns from a fortnight holiday in Cyprus with a tan and numerous scaly hypopigmented lesions on the neck and upper trunk.

What is the most likely diagnosis?

(Please select 1 option)

- Chronic plaque psoriasis
- Discoid eczema
- Pityriasis rosea
- **Pityriasis versicolor** ✓ Correct
- Seborrhoeic dermatitis

Pityriasis versicolor is caused by a superficial fungal infection with *Pityrosporum ovale*.

It usually presents as slightly scaly hypopigmented lesions. Growth is encouraged by an increase in temperature and suntan oils, and is most commonly seen after a sun holiday.

Chronic plaque psoriasis, discoid eczema and seborrhoeic dermatitis have distinct appearance and distribution.

Pityriasis rosea usually starts with a herald patch followed by small scaly lesions following the rib lines.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 17 mins 43 secs

Question: 29 of 82

A 52-year-old female presents with blistering of the hands and arms which deteriorates during the summer. She is otherwise well and drinks approximately 20 units of alcohol weekly.

Examination of her skin revealed erosions and scarring on the backs of her hands and forearms, and some mild hirsutism.

Which one of the following is the most likely diagnosis?

(Please select 1 option)

- Acute intermittent porphyria
- Erythropoietic protoporphyria
- Pemphigoid
- Porphyria cutanea tarda (PCT)
- Subacute lupus erythematous (LE)

A 52-year-old female presents with blistering of the hands and arms which deteriorates during the summer. She is otherwise well and drinks approximately 20 units of alcohol weekly.

Examination of her skin revealed erosions and scarring on the backs of her hands and forearms, and some mild hirsutism.

Which one of the following is the most likely diagnosis?

(Please select 1 option)

- Acute intermittent porphyria
- Erythropoietic protoporphyria
- Pemphigoid
- **Porphyria cutanea tarda (PCT)** ✓ Correct
- Subacute lupus erythematous (LE)

The history of photosensitive eruption, hypertrichosis and milia formation (keratin-containing cysts) are characteristic of PCT.

Acute intermittent porphyria usually causes intermittent neurological and abdominal problems.

Subacute LE can cause erythema and scarring, but in a patient with increased alcohol intake and hypertrichosis the most likely diagnosis is PCT.

Erythropoietic protoporphyria patients get pain and erythema on exposure to sunlight.

Urine protein	++
Blood	-
White cells	-

Which of the following is the most likely diagnosis?

(Please select 1 option)

- Acute tubular necrosis
- Churg-Strauss syndrome
- Interstitial nephritis ✓ Correct
- Membranous nephropathy
- Pyelonephritis

The rapid onset of renal failure, coupled with a rash and eosinophilia is highly suspicious of a diagnosis of interstitial nephritis as a result of exposure to non-steroidal or amoxicillin.

Whilst eosinophilia is not usually seen in interstitial nephritis as a result of NSAIDs, it is seen in penicillin induced interstitial nephritis.

CT scanning and ultrasound are the main imaging modalities, with IVU being rarely used now. Renal biopsy is definitive in cases where the diagnosis is in doubt.

Resolution of renal failure usually begins after the causative agent is discontinued.

Work Smart Session - MRCP Part 1

Question: 3 of 82

A 45-year-old man is referred to the dermatology clinic, with an intensely itchy, red, scaling rash which affects his scalp predominantly and is worse in spring and winter time. He also has a patch on his chest and around his beard.

On examination he has a severe scalp rash with crusting and scaling of skin.

Investigations show

Haemoglobin	13.1 g/dl	(13.5-18)
White cell count	5.9 x 10^9/l	(4-10)
Platelets	192 x 10^9/l	(150-400)
Sodium	139 mmol/l	(134-143)
Potassium	4.3 mmol/l	(3.5-5)
Creatinine	101 µmol/l	(60-120)
Scalp biopsy	Hyperkeratosis, acanthosis and focal spongiosis	

He tells you he cares most about his scalp.

Which of the following is the most appropriate first line treatment for him?

(Please select 1 option)

- Coal tar shampoo
- Ketoconazole shampoo

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 22 mins 36 secs

Question: 31 of 82

A 25-year-old female presents with red crusted lesions around the mouth and finger pulps, three months after having had small bowel resection for Crohn's disease.

What is the most likely cause of her skin condition?

(Please select 1 option)

- ○ Nicotinamide deficiency
- ○ Pyridoxine deficiency
- ○ Thiamine deficiency
- ○ Vitamin B_{12} deficiency
- ◉ Zinc deficiency ✓ Correct

Zinc deficiency can lead to acrodermatitis which presents with perioral dermatitis, acral involvement and sometimes alopecia.

The features of this patient who had bowel resection suggest zinc deficiency.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 23 mins 26 secs

Question: 32 of 82

A 16-year-old girl is seen in clinic as she is concerned due to areas of hair loss on the scalp.

Past medical history includes atopic eczema and she has a number of depigmented areas on her hands.

What is the most likely diagnosis?

(Please select 1 option)

◉	Alopecia areata ✓ Correct
○	Hypothyroidism
○	Seborrhoeic dermatitis
○	Systemic lupus erythematosus
○	Trichotillomania

This girl has a combination of vitiligo and alopecia areata which can co-exist and have similar autoimmune aetiology.

Discrete areas of hair loss and normal texture on the scalp are highly suggestive of alopecia areata.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 24 mins 8 secs

Question: 33 of 82

A 70-year-old female presents with a four month history of a dry, pruritic rash affecting the upper back and shins.

What is the most appropriate initial management of this patient?

(Please select 1 option)

○	Avoidance of contact irritants
○	Emollients ← This is the correct answer
○	Skin biopsy
◉	Take a detailed history to ascertain contact allergen ✕ Incorrect answer selected
○	Topical corticosteroids

This lady is likely to have asteatotic eczema which is a common problem and will improve just with plain emollients.

Xerotic skin is commoner in the elderly population especially in the winter months due to the dry heat from central heating.

All the other suggestions may be appropriate in a patient resistant to first line treatment but the first line is to try emollients.

- The lesions will be present for at least 24 hours
- There is likely to be a nut allergy

The commonest form of urticaria is idiopathic and there is no identifiable trigger.

Peanut allergy and penicillin may cause urticarial rashes but there is usually an associated specific history of contact with the allergen.

Urticarial lesions last less than 24 hours usually.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 25 mins 23 secs

Question: 35 of 82

A 36-year-old female presents with raised erythematous tender lesions on both legs which have developed since she had a throat infection two weeks ago.

Which one of the following investigations is most likely to establish the diagnosis?

(Please select 1 option)

- Anti-streptolysin-O titre (ASOT)
- Chest x ray
- Throat swab cultured for bacteria
- Mantoux test
- Throat swab cultured for viruses

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 26 mins 16 secs

Question: 35 of 82

A 36-year-old female presents with raised erythematous tender lesions on both legs which have developed since she had a throat infection two weeks ago.

Which one of the following investigations is most likely to establish the diagnosis?

(Please select 1 option)

○	Anti-streptolysin-O titre (ASOT) ← This is the correct answer
◉	Chest x ray ✕ Incorrect answer selected
○	Throat swab cultured for bacteria
○	Mantoux test
○	Throat swab cultured for viruses

This lady presents with tender lesions two weeks after a sore throat.

This is most likely to be post-streptococcal erythema nodosum and ASOT is most likely to confirm this.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 26 mins 16 secs

Question: 36 of 82

A 41-year-old female presents with a six month history of a pruritic vesicular-papular rash on the elbows, knees and buttocks associated with numerous blistering eruptions and excoriations.

Her GP has prescribed topical steroid therapy but this has not helped.

What is the most likely diagnosis?

(Please select 1 option)

- Atopic eczema (dermatitis)
- Dermatitis herpetiformis (DH)
- Lichen planus
- Psoriasis
- Scabies

A 41-year-old female presents with a six month history of a pruritic vesicular-papular rash on the elbows, knees and buttocks associated with numerous blistering eruptions and excoriations.

Her GP has prescribed topical steroid therapy but this has not helped.

What is the most likely diagnosis?

(Please select 1 option)

○	Atopic eczema (dermatitis)
◉	Dermatitis herpetiformis (DH) ✓ Correct
○	Lichen planus
○	Psoriasis
○	Scabies

This patient presents with pruritic vesicles on her elbows, knees and buttocks which have not responded to topical steroids. This is the classical presentation of DH.

Atopic dermatitis usually is flexural and responds to topical steroids.

Henoch-Schönlein purpura is a form of vasculitis.

In scabies there are burrows and in psoriasis the rash consists of plaques with silvery scales.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 29 mins 7 secs

Question: 37 of 82

A 17-year-old boy is diagnosed with scabies.

Which of the following statements regarding scabies is correct?

(Please select 1 option)

- Is best treated by salicylate emulsion
- It can be spread by a droplet infection
- It causes itchiness in the skin even where there is no obvious lesion to be seen
- It is caused by *Staphylococcus aureus*
- Typically affects the face

○	Is best treated by salicylate emulsion
○	It can be spread by a droplet infection
○	It causes itchiness in the skin even where there is no obvious lesion to be seen ← This is the correct answer
○	It is caused by *Staphylococcus aureus*
◉	Typically affects the face ✕ Incorrect answer selected

Scabies is an infestation of the skin with the microscopic mite *Sarcoptes scabei*. Infestation is common, found worldwide, and affects people of all races and social classes.

Scabies spreads rapidly under crowded conditions where there is frequent skin-to-skin contact between people, such as in hospitals, institutions, child-care facilities, and nursing homes.

Scabies can spread by direct, prolonged, skin-to-skin contact, with a person already infested with scabies. Contact must be prolonged (a quick handshake or hug will usually not spread infestation).

Infestation is easily spread to sexual partners and household members. Infestation may also occur by sharing clothing, towels, and bedding.

Scabies is characterised by papular-like irritations, burrows or rash of the skin, especially:

- the webbing between the fingers

- the skin folds on the wrist, elbow, or knee

- the penis

Scabies spreads rapidly under crowded conditions where there is frequent skin-to-skin contact between people, such as in hospitals, institutions, child-care facilities, and nursing homes.

Scabies can spread by direct, prolonged, skin-to-skin contact, with a person already infested with scabies. Contact must be prolonged (a quick handshake or hug will usually not spread infestation).

Infestation is easily spread to sexual partners and household members. Infestation may also occur by sharing clothing, towels, and bedding.

Scabies is characterised by papular-like irritations, burrows or rash of the skin, especially:

- the webbing between the fingers

- the skin folds on the wrist, elbow, or knee

- the penis

- the breast or

- shoulder blades.

A number of treatments are available for scabies, including:

- permethrin ointment

- benzyl benzoate and

- oral ivermectin for resistant cases.

Antihistamines and calamine lotion may be used to alleviate itching.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 30 mins 12 secs

Question: 38 of 82

A 15-year-old boy was treated with permethrin cream for scabies infestation.

On follow-up three weeks later he was found to have continuing infestation.

What is the most likely reason for this?

(Please select 1 option)

- Facial skin was not treated
- Non-disposal of underwear
- Other household members were not treated
- The organism is resistant to permethrin
- The treatment was not repeated as prescribed

A 15-year-old boy was treated with permethrin cream for scabies infestation.

On follow-up three weeks later he was found to have continuing infestation.

What is the most likely reason for this?

(Please select 1 option)

○	Facial skin was not treated
○	Non-disposal of underwear
◉	Other household members were not treated ✓ Correct
○	The organism is resistant to permethrin
○	The treatment was not repeated as prescribed

Scabies is an intensely pruritic and highly contagious infestation of the skin acquired through close personal contact.

A delayed type IV hypersensitivity reaction to the mites, their eggs, or excreta occurs approximately 30 days after infestation and is responsible for the intense pruritus that is the hallmark of the disease.

All household members and close personal contacts should be treated whether or not they are symptomatic and patients should be re-examined two weeks after treatment to evaluate effectiveness.

Treatment failures are uncommon. Recurrence of the eruption usually means re-infection has occurred.

In the treatment of psoriasis, which of the following statements is correct?

(Please select 1 option)

○	Etanercept is not effective in psoriatic arthritis
◉	Infliximab is associated with tuberculosis ✓ Correct
○	PUVA is ineffective
○	Retinoids are the most useful monotherapy in psoriatic patients
○	Vitamin D analogues are associated with cutaneous atrophy

Psoralen and ultraviolet light (PUVA) is an effective treatment for psoriasis, but has been related to increased risk of squamous cell carcinoma, and possibly malignant melanoma.

Retinoids are most effective in combination therapy, especially with ultraviolet B (UVB) phototherapy and PUVA.

Part of the attraction of vitamin D analogues over steroids is that they do not cause cutaneous atrophy, whereas steroids do.

The recombinant tumour necrosis factor and receptor fusion protein, etanercept, has demonstrated considerable beneficial effects on psoriatic arthropathy in placebo controlled, double blind studies.

Infliximab is associated with tuberculosis, by reactivation of latent disease. Thus it is advised that patients who are to be treated with infliximab are tuberculin tested, and if required, receive chest radiography.

Creatinine	101 µmol/l	(60-120)
Scalp biopsy	Hyperkeratosis, acanthosis and focal spongiosis	

He tells you he cares most about his scalp.

Which of the following is the most appropriate first line treatment for him?

(Please select 1 option)

- (●) Coal tar shampoo ✕ Incorrect answer selected
- ( ) Ketoconazole shampoo ← This is the correct answer
- ( ) Oral prednisolone
- ( ) Tacrolimus ointment
- ( ) Topical betamethasone

This man has seborrhoeic dermatitis which tends to affect hair bearing areas of skin with the scalp the worst affected.

It is thought that, at least in part, the activity of activated T cells may be enhanced by an increased reservoir of *Malassezia* yeasts. As such, regular washing of the hair with a ketoconazole based shampoo has been shown to reduce the severity of the condition.

Topical corticosteroids have been shown to hasten recovery, but may be associated with a rebound effect and rapid recurrence of the rash when they are withdrawn.

Coal tar shampoo and topical tacrolimus are alternate treatments.

Question: 4 of 82

A 31-year-old woman comes to the dermatology clinic complaining that a mole on her forearm has changed shape, enlarging to nearly three quarters of a centimetre in diameter, and although it was previously homogeneous in colour, parts of it have now become a very dark black.

She has no significant past medical history but admits to significant use of tanning beds and having spent a few years living in California.

Investigations show

Haemoglobin	13.0 g/dl	(13.5-18)
White cell count	5.4 x 10^9/l	(4-10)
Platelets	200 x 10^9/l	(150-400)
ESR	11 mm/hr	(1-20)
Sodium	139 mmol/l	(134-143)
Potassium	4.2 mmol/l	(3.5-5)
Creatinine	110 µmol/l	(60-120)

Excision biopsy: 5 mm thick lesion, no ulceration.

Which of the following features is most associated with a poor prognosis in this patient?

(Please select 1 option)

- (●) Depth of the melanoma lesion
- ( ) Female sex

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 32 mins 22 secs

Question: 40 of 82

Which of the following statements regarding psoriasis is most true?

(Please select 1 option)

○	Ciclosporin is ineffective in the treatment of psoriasis
○	Diagnosis requires histological confirmation
◉	Guttate psoriasis often arises after staphylococcal infection ✕ Incorrect answer selected
○	T-cells play a prominent role in the pathogenesis of psoriasis ← This is the correct answer
○	Twin studies have identified no genetic basis for psoriasis

Diagnosis of psoriasis is based on clinical observation of sharply demarcated, erythematous, scaling plaques, and rarely requires biopsy.

Streptococcal infection is associated with precipitation and recurrence of guttate psoriasis.

Ciclosporin is a major inhibitor of T cell activation, and, given that T cells are central to the pathogenesis of psoriasis, is very effective treatment in psoriasis.

Genetic studies have led most experts to believe that psoriasis is the result of multiple genetic factors interacting with environmental stimuli. Genetic factors also seem to contribute to the clinical manifestations of the disease, for example, age of onset and severity of disease.

○	1% of patients have associated psoriatic arthropathy
○	Guttate psoriasis is the most common form of the disease
○	Psoriasis is more common at lower geographical altitudes
◉	Psoriatic arthropathy precedes cutaneous lesions in roughly 20% of cases ✓ Correct
○	The prevalence in the United Kingdom is 10%

The prevalence of psoriasis is reported as between 0.5 and 4.6%.

For reasons which may be explained by the filtering of ultraviolet B (UVB) light, psoriasis is more common at higher altitudes.

The commonest form of psoriasis is plaque psoriasis, making up approximately 80% of cases (guttate -10%, erythrodermic - 3%, pustular - 3%).

Studies report:

- A 5-42% prevalence of psoriatic arthropathy in patients with cutaneous psoriasis and
- Arthropathy precedes cutaneous lesions in 20%
- Cutaneous lesions precede joint disease in 60-70% and
- They occur simultaneously in 10-20%.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 32 mins 59 secs

Question: 42 of 82

A 69-year-old woman presented with an ulcer over the left ankle, which had developed over the previous nine months. She had a history of right deep vein thrombosis (DVT) five years previously.

On examination she had a superficial slough-based ulcer, 6 cm in diameter, over the medial malleolus with no evidence of cellulitis.

Which one of the following is the most appropriate next investigation?

(Please select 1 option)

- Ankle-brachial pressure index
- Bacteriological swab of the ulcer
- Bilateral lower limb arteriogram
- Right leg venogram
- Venous duplex ultrasound scan

Which one of the following is the most appropriate next investigation?

(Please select 1 option)

◉	Ankle-brachial pressure index ✓ Correct
○	Bacteriological swab of the ulcer
○	Bilateral lower limb arteriogram
○	Right leg venogram
○	Venous duplex ultrasound scan

It has been reported that venous ulcerations are the most common type of ulcer affecting the lower extremities. The probable underlying cause of venous congestion, which may promote ulceration, is venous insufficiency.

The treatment of venous ulceration is control of oedema, treating any infection, and compression. However, compressive dressings or devices should not be applied if the arterial circulation is impaired.

It is thus important to identify any arterial disease, and ankle-brachial pressure index is a simple way of doing this. One may then progress to lower limb arteriogram if indicated.

There is no clinical sign of infection, and although a bacterial swab would help to rule out pathogens within the ulcer, arterial insufficiency is the more important issue.

If there is a clinical suspicion of DVT then duplex (or rarely a venogram) is indicated to decide on the indication for warfarin.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 35 mins 39 secs

Question: 43 of 82

A 35-year-old woman presents with a facial rash which had been present for one year.

On examination she had erythematous, scaly, indurated plaques on both cheeks with areas of scarring alopecia. Hyperkeratosis over dilated hair follicles was also seen.

What is the diagnosis?

(Please select 1 option)

- Acne rosacea
- Discoid lupus erythematosus ✓ Correct
- Impetigo
- Lupus pernio
- Psoriasis

The patient has discoid lupus as suggested by the indurated plaques on cheeks, the scarring alopecia and hyperkeratosis over the hair follicles.

A 24-year-old female attends clinic complaining of numerous depigmented areas on the arms and legs.

Which of the following diseases is most likely to accompany this skin condition?

(Please select 1 option)

○	Addison's disease
○	Hypoparathyroidism
◉	Pernicious anaemia ✓ Correct
○	Systemic lupus erythematosus
○	Tuberous sclerosis

The suggested diagnosis is vitiligo which is associated with numerous autoimmune conditions including, in order of frequency:

1. Autoimmune hypothyroidism
2. Pernicious anaemia
3. Alopecia areata
4. Addison's disease.

It is associated with both type 1 and 2 autoimmune polyendocrine syndromes but these are much rarer than the former diagnoses.

Questions Set : REF5123
Page Safety Tools

○	Acanthosis nigricans
○	Dysplastic naevus syndrome
○	Mastocytosis
◉	Neurofibromatosis ✓ Correct
○	Tuberous sclerosis

The patient is likely to have neurofibromatosis (NF1).

To be given the diagnosis of NF1, an individual must have at least two of the following features. Some people with NF1 have only two, while others can have several of these features:

- Six or more café-au-lait spots, or coffee-coloured birthmarks, each measuring over an inch in adults (1/4 inch in children)
- Two of more neurofibromas or a plexiform neurofibroma
- Freckles under the arm or in the groin region
- A tumour of the nerve to the eye called an optic glioma
- Two or more spots on the iris of the eye called Lisch nodules
- A problem of one of the bones such as bowing of a leg, with or without a fracture
- A parent, brother, sister, or child with NF1.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 36 mins 51 secs

Question: 46 of 82

A 55-year-old woman presents with a non-pruritic rash that had developed over the last two months. Examination revealed several, circular, erythematous, raised, smooth-surfaced lesions of variable size from 1-5 cm in diameter on the elbows, extensor aspects of the forearms and knuckles.

What is the most likely diagnosis?

(Please select 1 option)

- Eczema
- Granuloma annulare
- Psoriasis
- Tinea corporis
- Urticaria

What is the most likely diagnosis?

(Please select 1 option)

○	Eczema
○	Granuloma annulare ← This is the correct answer
○	Psoriasis
◉	Tinea corporis ✕ Incorrect answer selected
○	Urticaria

The history of non-itchy, circular, raised, smooth-surfaced lesions on the elbows, extensor aspects of the forearms and knuckles and the raised borders are suggestive of granuloma annulare.

Discoid eczema tends to be scaly and pruritic in nature.

Psoriasis typically has a silvery scale and can be pruritic.

Urticaria lasts a few hours and is pruritic.

Tinea corporis is a fungal infection and is typically scaly and pruritic in nature.

The most likely answer is therefore granuloma annulare. This can be associated with diabetes.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 38 mins 37 secs

Question: 47 of 82

A 70-year-old woman complained of a rash that had developed over a month. She had otherwise been fit and well. On examination, there were numerous tense, fluid filled blisters over the trunk and limbs, but no mucosal involvement was evident.

What is the most likely diagnosis?

(Please select 1 option)

- Dermatitis herpetiformis
- Erythema multiforme
- Herpes simplex
- Pemphigoid
- Pemphigus vulgaris

What is the most likely diagnosis?

(Please select 1 option)

○	Dermatitis herpetiformis
○	Erythema multiforme
○	Herpes simplex
○	Pemphigoid ← This is the correct answer
◉	Pemphigus vulgaris ✕ Incorrect answer selected

The patient presents with tense blisters on her arms, trunk and legs. She is otherwise well and there is no mucosal involvement. This is typical of bullous pemphigoid.

Dermatitis herpetiformis presents with itchy excoriated areas in the elbows knees and buttocks.

Erythema multiforme presents with characteristic target lesions.

Herpes simplex is vesicular and in generalised cases the patient is likely to be unwell.

Pemphigus presents with superficial erosions and usually there is mucosal involvement.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 39 mins 35 secs

Question: 48 of 82

A 60-year-old woman presents with raised, erythematous lesions on the limbs and blistering in the mouth and eyes. She had been taking a number of drugs prescribed by her GP.

Which may be responsible for her presentation?

(Please select 1 option)

- Nifedipine
- Paracetamol
- Paroxetine
- Prednisolone
- Sulphasalazine

Sulphasalazine ✓ Correct

This is a typical case of Stevens-Johnson syndrome.

Stevens-Johnson syndrome (SJS) is an immune-complex-mediated hypersensitivity complex that is a severe expression of erythema multiforme. It is now known also as erythema multiforme major.

SJS typically involves the skin and the mucous membranes. While minor presentations may occur, significant involvement of:

- oral
- nasal
- eye
- vaginal
- urethral
- gastrointestinal (GI)
- lower respiratory tract mucous membranes

may develop in the course of the illness.

GI and respiratory involvement may progress to necrosis.

SJS is a serious systemic disorder with the potential for severe morbidity and even death.

The drugs most closely associated with causing Stevens-Johnson syndrome are:

- antibacterials

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 40 mins 18 secs

Question: 49 of 82

A 65-year-old female who has a history of long-standing psoriasis and heavy alcohol intake, presents with a severe exacerbation of psoriasis. She was admitted and received topical therapy and over the month of her admission, her gamma-GT concentration had fallen from 400 U/L to 150 U/L (4-35).

Six weeks after discharge she was seen in outpatients where her psoriasis remained under control, but she complained of generalised hair loss.

What is the most likely cause for her hair loss?

(Please select 1 option)

- Alopecia areata
- Iron deficiency
- Telogen effluvium
- Thiamine deficiency
- Trichotillomania

What is the most likely cause for her hair loss?

(Please select 1 option)

◉	Alopecia areata ✕ Incorrect answer selected
○	Iron deficiency
○	Telogen effluvium ← This is the correct answer
○	Thiamine deficiency
○	Trichotillomania

In a normal healthy person's scalp about 85% of the hair follicles are actively growing hair and 15% are resting.

If there is some shock to the system, as many as 70% of the scalp hairs can be precipitated into a resting state, thus reversing the usual ratio. Typical precipitants include illnesses, operations, accidents and childbirth.

The resting scalp hairs, now in the form of club hairs, remain firmly attached to the hair follicles at first. It is only about two months after the shock that the new hairs coming up through the scalp push out the 'dead' club hairs and increased hair fall is noticed. Thus, paradoxically, with this type of hair loss, hair fall is a sign of hair regrowth.

As the new hair first comes up through the scalp and pushes out the dead hair a fine fringe of new hair is often evident along the forehead hairline. At first the fall of club hairs is profuse and a general thinning of the scalp hair may become evident but after several months a peak is reached and hair fall begins to lessen, gradually tapering back to normal over six to nine months.

As the hair fall tapers off the scalp thickens back up to normal, but recovery may be incomplete in some cases.

Sodium	139 mmol/l	(134-143)
Potassium	4.2 mmol/l	(3.5-5)
Creatinine	110 µmol/l	(60-120)

Excision biopsy: 5 mm thick lesion, no ulceration.

Which of the following features is most associated with a poor prognosis in this patient?

(Please select 1 option)

- (●) Depth of the melanoma lesion ✓ Correct
- ( ) Female sex
- ( ) Her age
- ( ) Lack of ulceration
- ( ) Significant exposure to sun beds

Survival is strongly correlated with depth of melanoma at the point of diagnosis, with lesions over 4 mm thick being associated with a particularly poor outcome.

Other predictors of a poor outcome include increasing age and male sex.

Ulceration of the lesion also implies greater risk of metastases. For lesions over 4 mm thick with ulceration, five year survival is less than 50%.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 42 mins 47 secs

Question: 50 of 82

A 20-year-old male presents with extensive, coalescing, hypopigmented, slightly scaly lesions on his back and chest.

The rash had been present for two years and had gradually become more extensive. He had otherwise been in good health. The lesions were not symptomatic but he was concerned about their appearance.

What is the most appropriate treatment for his condition?

(Please select 1 option)

- Aciclovir cream
- Ketoconazole cream
- Nystatin cream
- Oral itraconazole
- Oral terbinafine

(Please select 1 option)

○	Aciclovir cream
◉	Ketoconazole cream ✓ Correct
○	Nystatin cream
○	Oral itraconazole
○	Oral terbinafine

The patient presents with an asymptomatic eruption on his trunk. The lesions are scaly, hypopigmented and are not associated with any systemic disease. This is characteristic of pityriasis versicolor, which is caused by the unicellular yeast *Pityrosporum ovale* and *Pityrosporum orbiculare*. The yeast is lipophilic and is encouraged by an increase in environmental temperature, thus many patients notice that the condition begins after a summer vacation.

It is a disorder of the healthy, but the immunocompromised are at risk.

The condition is asymptomatic and appears pale in comparison to the normal skin. The fungus affects the melanocytes hence the hypo-pigmentation.

The treatment options include topical imidazole creams, selenium sulphide shampoo and, if not responding to topical treatment, oral itraconazole 200 mg once a day for seven days.

In this patient the topical treatment should be tried first.

What is the diagnosis?

(Please select 1 option)

○	Chronic mucocutaneous candidiasis
○	Iron deficiency
○	Ochronosis
○	Polychondritis
◉	Yellow nail syndrome ✓ Correct

This is yellow nail syndrome where the nails are yellow, thickened, curved, stop growing and may become detached from the nail bed.

Associated findings include lymphoedema, bronchiectasis and pleural effusions.

Questions Set : REF4716
Page Safety Tools

(Please select 1 option)

○	Bullous impetigo
◉	Bullous pemphigoid ✓ Correct
○	Insect bite
○	Scabies
○	Urticarial vasculitis

Pemphigoid, erythema multiforme and herpes are the commonest causes of a blistering rash.

The history above is a classic description of bullous pemphigoid (BP).

Immunoglobulin (Ig)G autoantibodies bind to the skin basement membrane in patients with BP. The binding of antibodies at the basement membrane activates complement and inflammatory mediators.

Activation of the complement system is thought to play a critical role in attracting inflammatory cells to the basement membrane. These inflammatory cells are postulated to release proteases, which degrade hemidesmosomal proteins and lead to blister formation.

Eosinophils are characteristically present in blisters as demonstrated by histopathologic analysis, although their presence is not an absolute diagnostic criterion.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 52 mins 4 secs

Question: 53 of 82

A 26-year-old male epileptic is admitted with temperature and rash.

Over the last one week a rash has developed and he has become increasingly ill. Recently he has had some problems with epileptic control and has commenced carbamazepine with valproate.

Examination reveals an unwell patient with a temperature of 39°C, a diffuse erythematous, painful rash with evidence of some lateral sliding of these erythematous areas on palpation.

There is also blistering and inflammation of the oral cavity.

What is the likely diagnosis?

(Please select 1 option)

- Erythema elevatum diutinum
- Exfoliative dermatitis
- Pustular psoriasis
- Toxic epidermal necrolysis
- Toxic shock syndrome

Favorites Suggested Sites Get More Add-ons
Questions Set : REF4638
Page Safety Tools

○	Pustular psoriasis
◉	Toxic epidermal necrolysis ✓ Correct
○	Toxic shock syndrome

This patient's presentation and clinical description suggests a diagnosis of toxic epidermal necrolysis (TEN) due to carbamazepine therapy.

TEN is a severe mucocutaneous exfoliative disease with an uncertain pathogenesis and a high mortality rate.

It is difficult to say whether it is another variant of Stevens-Johnson syndrome and treatment of both are similar.

It is often idiopathic but may be associated with:

- viral infections

- leukaemia

- lymphoma and

- drugs (in particular sulphonamides and anticonvulsants).

The suggested association with carbamazipine in this case makes toxic shock syndrome due to *Staph. aureus* remote, which like pustular psoriasis would not be expected to affect the mucous membranes.

Chest x ray shows bilateral hilar lymphadenopathy and clear lung fields. A clinical diagnosis of sarcoidosis is made.

Which one of the following is the most appropriate management plan?

(Please select 1 option)

○	24 hour urinary calcium measurement
◉	Follow up appointment with chest x ray in three months ✓ Correct
○	Mediastinoscopy and lymph node biopsy
○	Skin biopsy
○	Thoracic CT scan

This is also known as Löfgren's syndrome (a benign form of sarcoidosis).

The presentation of erythema nodosum-arthropathy-bilateral hilar lymphadenopathy syndrome is so characteristic that histological diagnosis is not necessary.

The prognosis is excellent with less than 10% having persistent disease.

With less characteristic presentations, positive biopsies are needed.

Mediastinoscopy is the method of choice for anterior mediastinal nodes.

Which of the following drugs is she most likely to have been prescribed?

(Please select 1 option)

- Erythromycin
- Isotretinoin
- Minocycline ✓ Correct
- Oxytetracycline
- Trimethoprim

Except trimethoprim, all other drugs listed above are used in the treatment of acne. All of these can cause hepatotoxicity.

Erythromycin usually causes cholestasis.

Minocycline can cause drug induced systemic lupus erythematosus (SLE).

A 50-year-old man presented in the summer complaining of itching and blistering of his hands and forehead.

On examination there were small areas of excoriation on the backs of his hands.

What is the most likely diagnosis?

(Please select 1 option)

- ○ Dermatitis herpetiformis
- ○ Lupus erythematosus
- ○ Pemphigoid
- ○ Pemphigus
- ◉ Porphyria cutanea tarda (PCT) ✓ Correct

The distribution of the lesions suggests a photosensitive element.

Both lupus erythematosus and PCT are associated with a photosensitive elements, however this is more typical of PCT.

PCT causes blistering of the hands and the forehead which usually heal with small scar and milia formation.

It is also associated with an excessive alcohol intake.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 58 secs

Question: 59 of 82

A previously fit 30-year-old female presents with a four day history of intractable pruritus and urticaria.

What is the most appropriate initial management?

(Please select 1 option)

- Chlorpheniramine
- Prednisolone
- Ranitidine
- Topical hydrocortisone
- Topical mepyramine

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 1 mins 49 secs

Question: 59 of 82

A previously fit 30-year-old female presents with a four day history of intractable pruritus and urticaria.

What is the most appropriate initial management?

(Please select 1 option)

○	Chlorpheniramine ← This is the correct answer
○	Prednisolone
○	Ranitidine
◉	Topical hydrocortisone ✕ Incorrect answer selected
○	Topical mepyramine

Urticaria is a common condition and usually responds very well to systemic antihistamines which are the correct first line treatment.

Oral steroids can be given for severe cases but only as a last resort.

Topical steroids/topical antihistamines have no effect.

Work Smart Session - MRCP Part 1

Time taken: 15 mins 16 secs

Question: 5 of 82

A 38-year-old woman has erythematous plaques with hyperpigmentation at the edge and central hypopigmentation. Serological tests are unremarkable and the patient is diagnosed with discoid lupus.

Which of the following therapeutic strategies is most appropriate initially?

(Please select 1 option)

- ○ Cyclophosphamide
- ○ Dapsone
- ○ Methotrexate
- ◉ Oral prednisolone ✕ Incorrect answer selected
- ○ Sun protective measures ← This is the correct answer

Discoid lupus is photosensitive and so avoiding the sun with protective clothing and sunscreens, and changing behaviour is important.

Topical or intradermal steroids and hydroxychloroquine are useful therapies to prevent scarring and new lesions appearing. The latter are less effective if patients continue to smoke.

If these treatments are ineffective, second line drugs such as methotrexate, azathioprine, or thalidomide may be used.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 1 mins 49 secs

Question: 60 of 82

A 74-year-old man with a thirty year history of psoriasis presented with generalised erythroderma of three days duration.

Examination reveals him to be shivering but otherwise well. He was treated as an in-patient with emollients and attention to fluid replacement and temperature control but failed to improve after five days.

What is the most appropriate next treatment?

(Please select 1 option)

- Oral hydroxychloroquine
- Oral methotrexate
- Oral prednisolone
- Topical coal tar
- Topical dithranol

Examination reveals him to be shivering but otherwise well. He was treated as an in-patient with emollients and attention to fluid replacement and temperature control but failed to improve after five days.

What is the most appropriate next treatment?

(Please select 1 option)

◉	Oral hydroxychloroquine ✕ Incorrect answer selected
○	Oral methotrexate ← This is the correct answer
○	Oral prednisolone
○	Topical coal tar
○	Topical dithranol

Erythroderma is an emergency as patients are susceptible to profound dehydration, infection and hypothermia.

Methotrexate would be the only correct treatment for someone with erythrodermic psoriasis.

Steroids could lead to unstable pustular psoriasis and would not generally work.

Hydroxychloroquine has little effect on psoriasis.

Topical coal tar and dithranol are good treatments for chronic plaque psoriasis but are highly irritant and would make the erythroderma much more inflamed and deteriorate his condition.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 3 mins 35 secs

Question: 61 of 82

A 40-year-old female presents with a six month history of pruritic papules, vesicles and excoriations on the elbows, knees, buttocks and scalp.

Her GP has prescribed topical betamethasone therapy which has been unhelpful.

What is the most likely diagnosis?

(Please select 1 option)

- Atopic dermatitis (eczema)
- Dermatitis herpetiformis (DH)
- Henoch-Schönlein purpura (HSP)
- Psoriasis
- Scabies

Her GP has prescribed topical betamethasone therapy which has been unhelpful.

What is the most likely diagnosis?

(Please select 1 option)

○	Atopic dermatitis (eczema)
◉	Dermatitis herpetiformis (DH) ✓ Correct
○	Henoch-Schönlein purpura (HSP)
○	Psoriasis
○	Scabies

The question describes the characteristic distribution of the lesions of dermatitis herpetiformis.

DH is one of the immunobullous conditions and characteristically has very intensely pruritic vesicles. It is not usually responsive to topical steroids, but would respond well to dapsone. It is associated with gluten sensitivity and coeliac disease.

Atopic eczema is non-vesicular and would respond to potent topical steroids.

HSP is a purpuric rash and is non-pruritic.

Scabies usually affect the extremities and rarely affect above the neck line. It does not cause papules and vesicles.

A 75-year-old female presents with chronic leg ulceration which is a consequence of venous insufficiency.

Which one of the following is the most appropriate management?

(Please select 1 option)

- Appropriate systemic antibiotic in preparation for skin grafting
- (●) Compression bandaging ✓ Correct
- Improve the venous return by limb elevation
- Skin biopsy to exclude neoplasm
- Vein surgery exclusion of neoplasm by skin biopsy

Venous ulcers are secondary to venous stasis and chronic stretching vessel of the vein walls of the superficial veins.

These eventually become thinner and ulcerate.

The only treatment shown in studies to be beneficial for this condition would be to compress the superficial venous using a four layer compression bandage.

The patient should always have their Doppler's and ABPI (ankle brachial pulse index) prior to compression. This should be greater than 1.

Increased fragility of the skin is characteristic of which of the following conditions?

(Please select 1 option)

○	Acute intermittent porphyria
○	Epidermolysis bullosa ← This is the correct answer
○	Neurofibromatosis
◉	Pseudo-xanthoma elasticum ✕ Incorrect answer selected
○	Tuberous sclerosis

Increased skin fragility is seen in a number of disorders and is used as a clinical test in bullous disorders (Nikolsky's sign).

Other causes include

- pemphigus vulgaris
- porphyria cutanea tarda
- drug reactions (especially pseudoporphyria).

Other causes of increased skin fragility (not associated with bullae) include long term corticosteroid therapy, Ehlers-Danlos syndrome and scurvy (vitamin C deficiency).

Shop

	Cerebral arteriovenous malformations ← This is the correct answer
◉	GI haemorrhage is the usual presenting feature ✕ Incorrect answer selected
	Telangiectasia of the mucous membranes, but not the skin
	Tendency of lesions to become less obvious with age

Hereditary Haemorrhagic Telangiectasia (HHT) is a multisystem vascular dysplasia characterised by the presence of multiple arteriovenous malformations (AVMs) that lack intervening capillaries and result in direct connections between arteries and veins. Small AVMs, called telangiectases, close to the surface of skin and mucous membranes often rupture and bleed.

The most common clinical manifestations are spontaneous and recurrent epistaxis and multiple telangiectases, which commonly appear on the lips, face, tongue or hands in adulthood. A minority of individuals with HHT have symptomatic GI bleeding, which most commonly begins after age 50 years. Large AVMs often cause symptoms when they occur in the brain or lung; complications from bleeding or shunting may be sudden and catastrophic.

In HHT there may also be pulmonary AVMs.

Epistaxis, not gastrointestinal (GI) haemorrhage, is the usual presenting feature.

Lesions become more obvious with age and affect mucous membranes as well as skin.

Oestrogen therapy is sometimes advocated but the effect, if any, is small.

Question: 65 of 82

Which is true regarding eczema herpeticum?

(Please select 1 option)

○	Is invariably fatal if untreated
○	Is more severe in reactivation disease
◉	Is typically associated with a high fever for over a week ✓ Correct
○	Only a single crop of vesicles usually appear
○	Usually has an indolent onset

Eczema herpeticum is the result of primary infection of eczematous skin with *Herpes simplex* virus (HSV). The severity varies from mild to fatal.

There is usually an abrupt onset with crops appearing over seven to nine days. These may become coalesced. Typically, the child has a high fever for seven days, and recurrent attacks can occur.

Death can result from physiological disturbances (loss of fluid electrolytes and protein through the skin) or dissemination of the virus to brain and other organs or from secondary bacterial sepsis.

Toxoplasmosis

Ulcerative colitis ← This is the correct answer

Erythema nodosum is characterised by painful, indurated, shiny, red, hot, elevated nodules 1-3 cm diameter particularly on the shins. There may be associated fever, malaise, and arthralgia ± hilar adenopathy.

Over a period of days they become violaceous, then dull purple, then fade like a large bruise without residual ulceration or scar. There may be crops over three to six weeks.

They are uncommon under the age of six, and are commoner in females than males.

Causes include:

1. *Infections*
   - Bacteria: Streptococci, leptospirosis, cat-scratch disease, psittacosis, yersinia.
   - Viruses: EBV.
2. *Other*
   - TB, tularaemia, histoplasmosis, coccidioidomycosis.
3. *Drugs*
   - Sulphonamides, oral contraceptive pill.
4. *Systemic diseases*
   - SLE, vasculitis, regional enteritis, ulcerative colitis, Behçet syndrome.

(Please select 1 option)

- It causes patches that fluoresce dull green under Wood's lamp ← This is the correct answer
- It is effectively treated with topical nystatin ointment
- It is most commonly caused by the fungus Microsporum canis ✕ Incorrect answer selected
- It often results in permanent alopecia
- Its presence should suggest immunological deficiency

Tinea capitis is a dermatophyte infection of the scalp most often caused by *Trichophyton tonsurans*, and occasionally by *Microsporum canis*. It is commonest in areas of socio-economic deprivation.

M. canis is a zoophilic species acquired from cats and dogs. There is initially a small papule at the base of the hair follicle which spreads peripherally forming a scaly circular plaque (ringworm) within which there are brittle, broken infected hairs (exclamation mark hairs).

Confluent patches of alopecia develop and there may be pruritis. Sometimes a severe inflammatory response produces an elevated boggy granulomatous mass (kerion), studded with sterile pustules. There may be fever and regional lymphadenopathy, and occasionally permanent scarring and alopecia may result.

The crusted patches fluoresce dull green under Wood's light. Microscopic examination of a potassium hydroxide (KOH) preparation shows tiny spores and the fungi may be grown in Sabouraud medium with antibiotics.

Oral griseofulvin for two to three months is required, or ketoconazole for resistant cases.

Question: 68 of 82

Which of the following suggests a diagnosis of molluscum contagiosum rather than chickenpox?

(Please select 1 option)

◉	Absence of erythema surrounding lesions ✓ Correct
○	Lesions disappearing within a month
○	Positive contact history
○	Presence of macules and papules
○	Presence of pruritis

Molluscum contagiosum is caused by a deoxyribonucleic acid (DNA) pox virus.

The lesions are small, skin coloured papules with central umbilication. There is little surrounding inflammation and they may be spread following scratching to other sites.

Chickenpox lesions in the early stages may be mistaken for molluscum. However, the presence of associated macules and later vesicles and pustules help to differentiate them.

These lesions also affect the mucus membranes, and usually disappear within a few weeks, while molluscum can persist for up to a year.

(Please select 1 option)

◉	He has coarctation of the aorta ✕ Incorrect answer selected
○	He has Eisenmenger's syndrome ← This is the correct answer
○	He has had a Blalock shunt operation
○	He is likely to have a loud continuous 'machinery' murmur below the left clavicle
○	He is likely to need urgent surgery

This is the differential cyanosis of a reversed patent ductus arteriosus (PDA). There is a right-left shunt from the pulmonary artery to the aorta just distal to the left subclavian artery.

Coarctation causes radiofemoral delay. It may be associated with PDA but there is no suggestion in this patient.

Continuous machinery murmur is the classic murmur of PDA but when the shunt reverses (as in patients with a large PDA and/or pulmonary disease) the murmur becomes softer and shorter.

When Eisenmenger's syndrome has developed surgery is associated with a very high mortality.

A Blalock shunt (anastomosis of subclavian artery to pulmonary artery) used to be performed for Fallot's tetralogy and leads to a weak left radial pulse.

Work Smart Session - MRCP Part 1

Question: 6 of 82

A 15-year-old boy comes to the dermatology clinic as his parents are concerned about some changes they have noticed in his skin. He is from a travelling community, and as such his parents have previously shunned medical services.

On examination you notice that he has a number of facial and periungual fibromata. He also has a number of hypomelanotic areas (at least four) on examination of his skin. You also notice gingival fibromata and pitting of his tooth enamel on examination of his mouth.

On which chromosome is the abnormality associated with this disease likely to be found?

(Please select 1 option)

○	Chromosome 2
◉	Chromosome 6 ✕ Incorrect answer selected
○	Chromosome 9 ← This is the correct answer
○	Chromosome 11
○	Chromosome 12

This boy has tuberous sclerosis, which is inherited in autosomal dominant fashion, with responsible defects having been identified on both chromosome 9 and chromosome 16. These chromosomes carry codes for hamartin and tuberin, protein gene products which are responsible for regulation of cell growth.

Most of the tumours which are produced in tuberous sclerosis are hamartomas, and various phenotypes of the disease occur, with some parents of patients having much more subtle features than those seen in their children.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 11 mins 19 secs

Question: 70 of 82

Which of the following is true of cutaneous anthrax?

(Please select 1 option)

- Causes a black eschar which overlies pus
- Is very likely to occur in subjects exposed to anthrax spores
- Lesions are associated with marked oedema
- Lesions are usually painful and tender
- Mortality is approximately 20% despite antibiotic therapy

Question: 70 of 82

Which of the following is true of cutaneous anthrax?

(Please select 1 option)

- ○ Causes a black eschar which overlies pus
- ○ Is very likely to occur in subjects exposed to anthrax spores
- ◉ Lesions are associated with marked oedema ✓ Correct
- ○ Lesions are usually painful and tender
- ○ Mortality is approximately 20% despite antibiotic therapy

Anthrax is caused by *Bacillus anthracis* a Gram-positive rod.

Cutaneous anthrax is caused by direct contact of the bacteria into an open wound (usually touching an infected animal). Cutaneous anthrax is associated with a black eschar without pus, tends to be painless and to have widespread oedema.

Without antibiotics mortality is of the order of 20%, but with antibiotics, mortality is low, which contrasts with pulmonary anthrax.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 12 mins

Question: 71 of 82

Which of the following concerning leg ulcers is correct?

(Please select 1 option)

- Diuretics have been shown to improve ulcer healing when associated with oedema
- In diabetic ulcers, the dressing should be left in situ for no more than one week
- Large gravitational ulcers are always painful
- Treating superficial infection with antibiotics has been shown to be beneficial
- Ulcers caused by arterial disease are typically treated by compression bandaging

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 12 mins 55 secs

Question: 71 of 82

Which of the following concerning leg ulcers is correct?

(Please select 1 option)

- Diuretics have been shown to improve ulcer healing when associated with oedema
- In diabetic ulcers, the dressing should be left in situ for no more than one week ← This is the correct answer
- Large gravitational ulcers are always painful
- Treating superficial infection with antibiotics has been shown to be beneficial ✕ Incorrect answer selected
- Ulcers caused by arterial disease are typically treated by compression bandaging

Diuretics may reduce oedema but have not been demonstrated per se to reduce healing time.

Gravitational ulcers are not usually painful.

If there are no obvious features of surrounding cellulitis, antibiotic therapy is usually unnecessary and has not been shown to improve healing in superficial infection which is common in ulceration.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 13 mins 20 secs

Question: 72 of 82

Which of the following is a recognised feature of psoriasis?

(Please select 1 option)

- ○ Angular stomatitis
- ○ Iridocyclitis
- ◉ Koebner phenomenon ✓ Correct
- ○ Loss of hair
- ○ Response to chloroquine

Psoriasis is associated with a dermopathy and arthropathy which may range from mild distal interphalangeal joint involvement with nail pitting to severe arthritis mutilans.

A Koebner phenomenon refers to outbreak of a skin eruption following minor trauma and is a feature of psoriasis.

Psoriatic arthropathy may be associated with an anterior uveitis.

Chloroquine may produce a severe attack of psoriasis.

Questions Set : REF4023
Page Safety Tools

(Please select 1 option)

○	It is characterised by flat scaly patches ← This is the correct answer
○	It is due to a fungal infection
◉	It is frequently associated with oro-genital itching ✕ Incorrect answer selected
○	May be preceded by intense itching
○	Tends to recur after apparent cure

Pityriasis rosea is a rash that can occur at any age, but it occurs most commonly in people between the ages of 10 and 35 years.

It may be set off by a viral infection but does not appear to be contagious; herpes viruses six and seven have most often been associated with pityriasis rosea. It is not caused by a fungus.

It is not related to foods, medicines, or stress. It most often affects teenagers or young adults.

The condition often begins as a large single pink patch on the chest or back. This patch may be scaly and is called a 'herald' or 'mother' patch.

Within a week or two, more pink patches, sometimes hundreds of them, appear on the body and on the arms and legs. Patches may also occur on the neck, and though rare, the face.

The oval patches follow the line of the ribs like a fir tree. They have a dry surface and may have an inner circlet of scaling.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 14 mins 12 secs

Question: 74 of 82

Which of the following may be responsible for an acute relapse of systemic lupus erythematosus (SLE) in a 38-year-old female?

(Please select 1 option)

- Hydralazine therapy
- Pregnancy
- Progesterone only contraceptive pill
- Salmeterol therapy
- Winter holiday in Lapland

Questions Set : REF4012
Page Safety Tools

- Pregnancy ✓ Correct
- Progesterone only contraceptive pill
- Salmeterol therapy
- Winter holiday in Lapland

Some physiological and environmental factors affect the periods of deterioration and of remission in systemic lupus erythematosus.

These factors include hormone replacement therapy (HRT) and particularly the oral contraceptive, pregnancy and infection. It would not be expected with the progesterone only oral contraceptive.

You would expect to find virtually no sun on a winter holiday in Lapland (Arctic circle)!

A number of drugs (hydralazine, procainamide, isoniazid, chlorpromazine, D-penicillamine and methyldopa) can result in drug-induced lupus in predisposed individuals.

This can be differentiated from the idiopathic SLE on genetic and immunologic grounds.

Furthermore,

- it is mild and reversible on stopping the drug
- renal disease and double stranded anti-DNA are rare (although antibodies specific for histones may be present)
- the sex ratio is equal.

These drugs do not cause deterioration in patients with SLE.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 14 mins 37 secs

Question: 75 of 82

A 43-year-old woman with atopic dermatitis (atopic eczema) presented with an acute generalised exacerbation of her disease.

She was admitted to hospital but failed to improve with emollients, topical betamethasone 17-valerate and oral antihistamine.

Which one of the following drugs is the most appropriate treatment?

(Please select 1 option)

- Acitretin
- Amoxicillin
- Cyclosporin
- Colchicine
- Dapsone

A 43-year-old woman with atopic dermatitis (atopic eczema) presented with an acute generalised exacerbation of her disease.

She was admitted to hospital but failed to improve with emollients, topical betamethasone 17-valerate and oral antihistamine.

Which one of the following drugs is the most appropriate treatment?

(Please select 1 option)

○	Acitretin
○	Amoxicillin
○	Cyclosporin ← This is the correct answer
○	Colchicine
◉	Dapsone ✕ Incorrect answer selected

Cyclosporin is a well used drug in the treatment of atopic dermatitis (AD). It is usually at doses of 2-5 mg/kg.

The pathophysiology of AD is complex but the T lymphocytes are involved and it is known that there is an increased production of cytokines particularly IL -4.

Cyclosporin is a suppressor of T cells and in that respect works very well in atopic dermatitis and psoriasis. The side effects of hypertension and renal toxicity limit its use.

These patients are seen monthly to have their blood pressure and urea and electrolytes (U&E) checked.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 19 mins 42 secs

Question: 76 of 82

A 22-year-old woman complains of haemoptysis, abdominal pains and pyrexia for a month.

She is admitted to hospital and found to be apyrexial and not distressed. There are numerous crusted, linear lesions on her forearms.

What is the most likely diagnosis?

(Please select 1 option)

- Acute intermittent porphyria
- Factitious disorder
- Systemic lupus erythematosus
- TB
- Wegener's granulomatosis

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 23 mins 54 secs

Question: 76 of 82

A 22-year-old woman complains of haemoptysis, abdominal pains and pyrexia for a month.

She is admitted to hospital and found to be apyrexial and not distressed. There are numerous crusted, linear lesions on her forearms.

What is the most likely diagnosis?

(Please select 1 option)

○	Acute intermittent porphyria
◉	Factitious disorder ✓ Correct
○	Systemic lupus erythematosus
○	TB
○	Wegener's granulomatosis

The history is very vague and the patient has no clinical features other than a rash which sounds typical of dermatitis artifacta.

The crusted lesions on the forearms suggest artefacta as this is the most typical site for these lesions.

Porphyria may be expected to have vesicles on sun exposed regions, face, arms and legs.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 25 mins 16 secs

Question: 77 of 82

A 40-year-old man presented with pityriasis versicolor.

What is the most appropriate treatment?

(Please select 1 option)

○	Methotrexate
○	Oral terbinafine
○	Phototherapy with ultraviolet light (UVB)
◉	Psoralen with ultraviolet light (PUVA) therapy ✕ Incorrect answer selected
○	Topical selenium sulphide ← This is the correct answer

Pityriasis versicolor (also called tinea versicolor) is a skin lesion caused by a fungus called *Malassezia furfur*.

The treatment is topical selenium sulphide. Oral itraconazole is also effective.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 26 mins 22 secs

Question: 78 of 82

What is the most common presenting feature of porphyria cutanea tarda?

(Please select 1 option)

- Acute blistering crises affecting the trunk and limbs
- Acute redness and swelling following sun exposure
- Erythroderma
- Generalised hypertrichosis
- Skin fragility and blistering affecting the hands, face and scalp ✓ Correct

Porphyria cutanea tarda (PCT) is a term that encompasses a group of related disorders, all of which arise from deficient activity of the haeme-synthetic enzyme uroporphyrinogen decarboxylase (URO-D) in the liver.

The porphyrins produced in PCT are photoactive molecules that absorb light energy strongly in the visible violet spectrum. Photoexcited porphyrins in the skin mediate oxidative damage to biomolecular targets, causing cutaneous photosensitivity reactions.

The most common presenting sign of PCT is fragility of sunexposed skin after mechanical trauma, leading to erosions and bullae, worst on dorsal hands, forearms and face.

(Please select 1 option)

○	Erythema induratum (EI) ← This is the correct answer
○	Erythema marginatum
○	Erythema nodosum
○	Lupus pernio
◉	Lupus vulgaris ✕ Incorrect answer selected

EI is a form of panniculitis characterised by chronic, recurrent, tender, subcutaneous, and sometimes ulcerated nodules on the lower legs that may also appear elsewhere.

Females are more frequently affected, with a female:male ratio of 7:1 and it is more frequent in younger females.

It is found in association with tuberculosis.

Another possibility although not provided in the stems is pyoderma gangrenosum.

On the other hand, lupus vulgaris is a chronic, progressive and destructive form of cutaneous tuberculosis in patients with a moderate or high degree of immunity. It occurs more commonly in females than in males.

The classical lesions consist of reddish-brown plaques not nodules. The lesions progress by peripheral extension and central healing, atrophy and scarring. The areas of predilection are head and neck (80%), followed by arms, legs, then trunk.

This rash is not the typical description of erythema marginatum (finer rash) or multiforme (blisters, targets).

Lupus pernio occurs in association with sarcoid.

Question: 9 of 82

Concerning neurofibromatosis type 1 (NF1), which one of the following statements is true?

(Please select 1 option)

- Bilateral acoustic neuromas are common
- Clinical severity in individuals is similar in a given family
- New mutations occur rarely
- Pigmented spots on the iris are a characteristic feature ✓ Correct
- The diagnosis is likely if two café au lait patches are present

Lisch nodules of the iris are present in more than 90% of patients.

Bilateral acoustic neuromas are a hallmark feature of neurofibromatosis type 2.

Expressivity of the gene is highly variable and members of the same family usually show wide differences in clinical symptoms.

NF1 is one of the most common autosomal dominant conditions. However almost half of all cases give no family history and are new mutations. The mutation rate is estimated to be 1:10,000 gametes.

The diagnosis is suggested by six or more café au lait macules (spots), each over 5 mm in diameter in prepubescent individuals and over 15 mm in post pubertal individuals.

Question: 1 of 100

A 40-year-old man is admitted to the Emergency Department after being involved in a house fire. He is extremely drowsy but you notice on examining him that he seems well perfused, with his cheeks looking almost pink. His BP is 100/60 and his pulse is 95 and regular. Blood gas analysis reveals a CO level of 12% and a metabolic acidosis with a pH of 7.15.

Which of the following is the most appropriate next intervention?

(Please select 1 option)

- **A** Hyperbaric oxygen
- **B** IV mannitol
- **C** IV sodium bicarbonate
- **D** 100% oxygen by mask
- **E** Nebulised salbutamol

Time taken: 37 mins 19 secs

Question: 10 of 100

A 50-year-old woman is found to have reversed splitting of the second heart sound.

This is found in which one of the following conditions?

(Please select 1 option)

- Atrial septal (AS) defect
- Mild aortic regurgitation
- Patent ductus arteriosus
- Right bundle branch block (RBBB)
- Ventricular septal defect (VSD)

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 37 mins 17 secs

Question: 100 of 100

A 63-year-old female presents with a one day history of confusion with headaches.

On examination she is confused, with a Glasgow Coma Scale of 13 and a temperature of 39.5°C.

She has nuchal rigidity and photophobia.

CSF examination reveals a glucose of 0.5 mmol/l (3.3-4.4), a white cell count of 2500 per mm and Gram-positive cocci in pairs.

Which of the following is correct?

(Please select 1 option)

○	A characteristic rash would be expected
○	Nerve deafness would be a common complication in this case
○	Rifampicin should be given to close contacts
○	The most likely infective organism is *Staphylococcus aureus*
○	The organism is likely to be penicillin resistant

Submit answer | Skip question | Tag Question | Remove question

She has nuchal rigidity and photophobia.

CSF examination reveals a glucose of 0.5 mmol/l (3.3-4.4), a white cell count of 2500 per mm and Gram-positive cocci in pairs.

Which of the following is correct?

(Please select 1 option)

○	A characteristic rash would be expected
◉	Nerve deafness would be a common complication in this case ✓ Correct
○	Rifampicin should be given to close contacts
○	The most likely infective organism is *Staphylococcus aureus*
○	The organism is likely to be penicillin resistant

This patient has pneumococcal meningitis, caused by the Gram-positive coccus *Strep. pneumoniae*.

This is the second commonest cause of bacterial meningitis (commonest in the elderly) and is associated with the highest mortality (20%) and highest morbidity, such as deafness which may occur in 50%.

Contacts do not require treatment and there is no rash associated with pneumococcal meningitis.

Meningococcus is Gram-negative.

Work Smart Session - MRCP Part 1

Time taken: 41 mins 7 secs

Question: 10 of 100

A 50-year-old woman is found to have reversed splitting of the second heart sound.

This is found in which one of the following conditions?

(Please select 1 option)

○	Atrial septal (AS) defect
○	Mild aortic regurgitation
○	Patent ductus arteriosus ← This is the correct answer
◉	Right bundle branch block (RBBB) ✕ Incorrect answer selected
○	Ventricular septal defect (VSD)

Reversed splitting of the second heart sound occurs with reversal of the normal A2, P2 pattern.

Thus A2 may be delayed as with severe AS (not mild), and LBBB.

P2 may be early as with Wolff-Parkinson-White type B and persistent ductus arteriosus.

Atrial septal defects show wide fixed splitting, and RBBB has wide, but not fixed splitting.

Work Smart Session - MRCP Part 1

Time taken: 41 mins 7 secs

Question: 11 of 100

A 35-year-old lady presented with left-sided weakness.

She has a young family with a 5-year-old son and a 2-year-old daughter. Previously she had two spontaneous abortions. After the birth of her last child she developed a deep vein thrombosis (DVT) and received three months of anticoagulation with warfarin.

On examination she has left-sided weakness with pyramidal signs. A CT head scan showed a right middle cerebral artery territory infarct.

Which of the following is the most likely diagnosis?

(Please select 1 option)

○	Hypertension
○	Kawasaki syndrome
○	Patent foramen ovale
○	Systemic lupus erythematosus
○	Thrombotic thrombocytopaenic purpura

Submit answer | Skip question | Tag Question | Remove question

Question: 11 of 100

A 35-year-old lady presented with left-sided weakness.

She has a young family with a 5-year-old son and a 2-year-old daughter. Previously she had two spontaneous abortions. After the birth of her last child she developed a deep vein thrombosis (DVT) and received three months of anticoagulation with warfarin.

On examination she has left-sided weakness with pyramidal signs. A CT head scan showed a right middle cerebral artery territory infarct.

Which of the following is the most likely diagnosis?

(Please select 1 option)

○	Hypertension
○	Kawasaki syndrome
○	Patent foramen ovale
◉	Systemic lupus erythematosus ✓ Correct
○	Thrombotic thrombocytopaenic purpura

This patient has a prothrombotic tendency suggestive of the lupus anticoagulant with recurrent abortions, previous DVT and now she has developed a left hemiparesis.

Work Smart Session - MRCP Part 1

Time taken: 42 mins

Question: 12 of 100

A 59-year-old male presents with a one hour history of central crushing chest pain. He is known to be diabetic, hypertensive and is a non-smoker.

On examination his pulse rate is 90 beats/min, blood pressure 130/85 mmHg, S1 S2 are audible with no murmurs. There is no evidence of cardiac failure.

An electrocardiogram (ECG) is performed.

Which of the following would be an indication for thrombolysis?

(Please select 1 option)

○	Atrial fibrillation greater than 150 min^{-1}
○	Right bundle branch block
○	ST depression of 2 mm in leads II, III, avF
○	ST elevation of 2 mm in V4-V6
○	Supraventricular tachycardia

Submit answer | Skip question | Tag Question | Remove question

(Please select 1 option)

○	Atrial fibrillation greater than 150 min^{-1}
○	Right bundle branch block
○	ST depression of 2 mm in leads II, III, avF
◉	ST elevation of 2 mm in V4-V6 ✓ Correct
○	Supraventricular tachycardia

This patient is having an acute myocardial infarction (MI); the ECG changes of ST elevation of 2 mm in V4-V6 suggest an anterolateral MI.

Given this history and ECG changes, he should be given thrombolytic treatment, along with aspirin, heparin, beta-blockade, statin therapy and subsequent angiotensin-converting enzyme (ACE) inhibition.

ECG criteria for thrombolysis include:

- ST elevation of more than 1 mm in standard limb leads
- ST elevation more than 2 mm in anterior chest leads
- new left bundle branch block

within 24 hours of typical pain.

Evidence beyond 12 hours of pain is equivocal thrombolysis at this time; it tends to be used if there is clinical deterioration or persistent pain.

Work Smart Session - MRCP Part 1

Time taken: 43 mins 4 secs

Question: 13 of 100

A 54-year-old obese male with a history of angina and hypertension presents with central crushing chest pain of two hours duration.

High flow oxygen, sublingual GTN and aspirin are administered and venous access is obtained. Whilst being attached to an ECG monitor he collapses and the initial rhythm is pulseless ventricular tachycardia (VT).

Which of the following is the most appropriate immediate treatment for this man?

(Please select 1 option)

○	A ventilation to compression ratio of 30:2 should commenced
○	Continuous chest compressions should be started
○	He should be defibrillated with a 200 J (monophasic) shock
○	He should be given a praecordial thump
○	Intravenous adrenaline should be given

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 54 year old obese male with a history of angina and hypertension presents with central crushing chest pain of two hours duration.

High flow oxygen, sublingual GTN and aspirin are administered and venous access is obtained. Whilst being attached to an ECG monitor he collapses and the initial rhythm is pulseless ventricular tachycardia (VT).

Which of the following is the most appropriate immediate treatment for this man?

(Please select 1 option)

○	A ventilation to compression ratio of 30:2 should commenced
○	Continuous chest compressions should be started
○	He should be defibrillated with a 200 J (monophasic) shock
◉	He should be given a praecordial thump ✓ Correct
○	Intravenous adrenaline should be given

An initial praecordial thump is indicated and is more likely to be successful in converting pulseless VT to sinus rhythm, than if the rhythm was ventricular fibrillation (VF).

The appropriate compression to ventilation ratio is 30:2, which should be synchronised to allow effective ventilation, until a laryngeal mask airway (LMA) or tracheal tube is passed.

When using a monophasic defibrillator all unsynchronised shocks are 360 J.

The first dose of adrenaline is given immediately before the third 360 J (monophasic) shock.

Work Smart Session - MRCP Part 1

Time taken: 44 mins 13 secs

Question: 14 of 100

A 32-year-old female smoker presents with acute severe asthma. The SaO2 are 80% on 15 L of oxygen and the pO2 is 8.2kPa (10.5-13).

There is widespread expiratory wheeze throughout the chest. She is given IV hydrocortisone, 100% oxygen and 5 mg of nebulised salbutamol.

What is the next step in your management?

(Please select 1 option)

- IV augmentin
- IV magnesium
- IV potassium
- IV theophylline
- Oral prednisolone

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

○	IV magnesium ← This is the correct answer
○	IV potassium
○	IV theophylline
◉	Oral prednisolone ✕ Incorrect answer selected

This question focuses on acute treatment of asthma.

Your initial approach should be SOS - salbutamol, oxygen and steroids intravenously (IV).

In the meantime a chest x-ray (CXR) should be organised to rule out pneumothorax.

You should then consider further efforts to treat bronchoconstriction - a silent chest, or a tiring patient should suggest ITU review.

The recommended dose of magnesium is 2 g over 30 minutes. The mechanism by which it has its effect is not fully understood, but it is thought that low magnesium levels in bronchial smooth muscle favour bronchoconstriction.

IV theophylline may be considered, but magnesium would be higher on the list.

IV antibiotic may be indicated, but your initial focus should be promoting bronchodilation.

IV potassium may be required as the beta agonists push down the potassium.

Oral prednisolone can wait, as you have already given IV hydrocortisone as part of your SOS approach.

Question: 15 of 100

A 22-year-old male is admitted wheezing with a respiratory rate of 35/min, a pulse of 120 beats per min, blood pressure 110/70 mmHg, peak expiratory flow rate <50% predicted.

The emergency medical services have administered salbutamol 5 mg (twice), ipratroprium 0.5 mg and face mask oxygen.

His arterial blood gas reveals:

pH	7.42	(7.36-7.44)
$PaCO_2$	5.0 kPa	(4.7-6.0)
PaO_2	22 kPa	(11.3-12.6)
Base excess	-2 mmol/l	(+/-2)
SpO_2	98	

Which of the following is the most appropriate action for this man?

(Please select 1 option)

- ○ Chest x ray
- ○ Intensive care referral
- ○ Ipratroprium
- ○ Magnesium 1-2 g
- ○ Oxygen 35 %

Base excess	-2 mmol/l	(+/-2)
SpO_2	98	

Which of the following is the most appropriate action for this man?

(Please select 1 option)

◉	Chest x ray ✕ Incorrect answer selected
○	Intensive care referral ← This is the correct answer
○	Ipratroprium
○	Magnesium 1-2 g
○	Oxygen 35 %

In this case the patient is showing signs of respiratory decompensation.

A normal or raised $PaCO_2$ in an asthmatic is a warning of impending respiratory failure as the patient becomes too tired to ventilate adequately and ITU need to be notified.

Administration of magnesium would be the next therapeutic measure.

A chest x ray will be helpful but should not delay in treatment and referral.

35 % oxygen is inadequate.

Work Smart Session - MRCP Part 1

Time taken: 48 mins 5 secs

Question: 16 of 100

A 22-year-old female is admitted very distressed and short of breath.

Examination reveals a respiratory rate of 35/min, a pulse of 120 beats per minute, a blood pressure 110/70 mmHg, oxygen saturations of 90% and a peak expiratory flow rate <50% predicted.

The emergency medical services have administered salbutamol 5 mg (twice) and face mask oxygen.

Which of the following is the most appropriate next action in this patient?

(Please select 1 option)

- Arterial blood gas analysis
- Intensive care referral
- Oxygen 35%
- Prednisolone 40 mg
- Salbutamol 5 mg and ipratroprium bromide 0.5 mg

Submit answer | Skip question | Tag Question | Remove question

Which of the following is the most appropriate next action in this patient?

(Please select 1 option)

○	Arterial blood gas analysis
◉	Intensive care referral ✕ Incorrect answer selected
○	Oxygen 35%
○	Prednisolone 40 mg
○	Salbutamol 5 mg and ipratroprium bromide 0.5 mg ← This is the correct answer

According to British Thoracic Society guidelines, addition of ipratroprium would be the next step in the case of this lady with acute severe asthma.

Prednisolone would be administered shortly thereafter.

35% oxygen is inadequate and a maximal concentration should be used.

A blood gas is not essential for management particularly with the oxygen saturations of 90% although these will be performed.

Intensive care referral may well be appropriate if this lady does not improve.

Work Smart Session - MRCP Part 1

Time taken: 49 mins 35 secs

Question: 17 of 100

A 27-year-old lady collapses in the Emergency Department after being admitted with numerous seizures.

You obtain information from her husband that she has a past history of seizures, but has not had any for the last two years, and is well controlled on valproate.

He also informs you that she has been gaining weight recently and has also had erratic menses which the neurology clinic attribute to the valproate.

Pulse	110/min
Blood pressure	160/90 mmHg
Urinalysis	3+ proteinuria

After airway, breathing and circulation, the immediate drug therapy should be:

(Please select 1 option)

- Diazepam 10 mg
- Lorazepam 2 mg
- Magnesium 2 grams
- Nil
- Phenytoin 1000 mg

Submit answer | Skip question | Tag Question | Remove question

He also informs you that she has been gaining weight recently and has also had erratic menses which the neurology clinic attribute to the valproate.

Pulse	110/min
Blood pressure	160/90 mmHg
Urinalysis	3+ proteinuria

After airway, breathing and circulation, the immediate drug therapy should be:

(Please select 1 option)

- ◉ Diazepam 10 mg ✕ Incorrect answer selected
- ○ Lorazepam 2 mg
- ○ Magnesium 2 grams ← This is the correct answer
- ○ Nil
- ○ Phenytoin 1000 mg

This lady may well be having an epileptic fit, but why should a young woman have an elevated blood pressure and proteinuria?

In a woman of this age with raised blood pressure and proteinuria, a diagnosis of eclampsia has to be considered and the primary treatment of eclampsia is the administration of magnesium.

Work Smart Session - MRCP Part 1

Time taken: 51 mins 49 secs

Question: 18 of 100

A 67-year-old man with insulin-dependent diabetes with a broad complex pulseless tachyarrhythmia (with a protected airway) has been defibrillated three times.

He has just finished receiving two minutes of cardiopulmonary resuscitation (CPR) and has received adrenaline.

Which of the following is the next step in the management of the arrest?

(Please select 1 option)

- Adrenaline 1 mg
- Amiodarone 300 mg
- DC shock
- Lidocaine 100 mg
- Removal of oxygen and then DC shock

Work Smart Session - MRCP Part 1

Time taken: 53 mins 27 secs

Question: 18 of 100

A 67-year-old man with insulin-dependent diabetes with a broad complex pulseless tachyarrhythmia (with a protected airway) has been defibrillated three times.

He has just finished receiving two minutes of cardiopulmonary resuscitation (CPR) and has received adrenaline.

Which of the following is the next step in the management of the arrest?

(Please select 1 option)

○	Adrenaline 1 mg
○	Amiodarone 300 mg ← This is the correct answer
◉	DC shock ✕ Incorrect answer selected
○	Lidocaine 100 mg
○	Removal of oxygen and then DC shock

After three DC shocks and a further cycle of two minutes of CPR the next step is amiodarone 300 mg intravenously and then a fourth shock.

If amiodarone is not available lidocaine is a suitable alternative.

Work Smart Session - MRCP Part 1

Time taken: 53 mins 27 secs

Question: 19 of 100

A 66-year-old man with insulin-dependent diabetes with a treated potassium of 5.4 mmol/l (3.5-5) and palpitations develops pulseless ventricular tachycardia. The anaesthetist is supporting airway and breathing.

Which of the following is the next step in his management?

(Please select 1 option)

- Adrenaline 1 mg
- Amiodarone 300 mg
- Cardiopulmonary resuscitation (CPR) 15:2 for two minutes
- Defibrillation at 150J biphasic
- Praecordial thump

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Work Smart Session - MRCP Part 1

Time taken: 54 mins 29 secs

Question: 19 of 100

A 66-year-old man with insulin-dependent diabetes with a treated potassium of 5.4 mmol/l (3.5-5) and palpitations develops pulseless ventricular tachycardia. The anaesthetist is supporting airway and breathing.

Which of the following is the next step in his management?

(Please select 1 option)

○	Adrenaline 1 mg
○	Amiodarone 300 mg
○	Cardiopulmonary resuscitation (CPR) 15:2 for two minutes
○	Defibrillation at 150J biphasic ← This is the correct answer
◉	Praecordial thump ✕ Incorrect answer selected

In the case of ventricular tachycardia and ventricular fibrillation immediate defibrillation is the treatment of choice.

The other options come further down the algorithm and CPR is now recommended at 30:2.

A praecordial thump can be administered immediately following a witnessed cardiac arrest.

Work Smart Session - MRCP Part 1

Time taken: 1 mins 47 secs

Question: 1 of 100

A 40-year-old man is admitted to the Emergency Department after being involved in a house fire. He is extremely drowsy but you notice on examining him that he seems well perfused, with his cheeks looking almost pink. His BP is 100/60 and his pulse is 95 and regular. Blood gas analysis reveals a CO level of 12% and a metabolic acidosis with a pH of 7.15.

Which of the following is the most appropriate next intervention?

(Please select 1 option)

○	**A** Hyperbaric oxygen
○	**B** IV mannitol
○	**C** IV sodium bicarbonate
◉	**D** 100% oxygen by mask ✓ Correct
○	**E** Nebulised salbutamol

The answer is D), 100% oxygen by mask. Hyperbaric oxygen is recommended by some countries including the US, although because of a lack of randomised control evidence it is not standard practice in the UK as there appears to be no significant improvement in outcome versus high flow oxygen alone. Sodium bicarbonate is not indicated, and IV mannitol is only used if there is suspicion of cerebral oedema. Key to prognosis is removal from the source of carbon monoxide as quickly as possible, and instigation of high flow oxygen treatment. At a level of 12%, long term psychological disturbance or memory loss is possible.

Work Smart Session - MRCP Part 1

Time taken: 55 mins 26 secs

Question: 20 of 100

A patient has just received intravenous ceftazidime. They immediately become flushed and wheezy, with a blood pressure of 80/40 mmHg.

Which of the following is the most appropriate immediate management for this patient?

(Please select 1 option)

○	Chlorphenamine 10 mg IV
○	Epinephrine 0.2 ml of 1:1000 IV
○	Epinephrine 0.5 mg IV
◉	Epinephrine 0.5 mg i.m. ✓ Correct
○	Hydrocortisone 100 mg IV

Immediate treatment of anaphylaxis includes cessation of whatever caused it.

Then give oxygen, fluids and adrenaline/epinephrine 0.5 mg intra-muscularly or subcutaneously.

Checking concentrations of adrenaline is very important especially in high pressure situations. Intravenous adrenaline is potentially hazardous unless diluted appropriately.

Work Smart Session - MRCP Part 1

Time taken: 55 mins 26 secs

Question: 21 of 100

You are on call for hospital at night and are urgently called to a patient on the ward who is choking on a piece of steak visible in his oropharynx. He is in extremis with saturations of 87%.

Which of the following is the most appropriate immediate management for this patient?

(Please select 1 option)

- Cricothyroidotomy
- Finger sweep
- Heimlich manoeuvre
- High flow oxygen
- Removal with forceps

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

You are on call for hospital at night and are urgently called to a patient on the ward who is choking on a piece of steak visible in his oropharynx. He is in extremis with saturations of 87%.

Which of the following is the most appropriate immediate management for this patient?

(Please select 1 option)

○	Cricothyroidotomy
○	Finger sweep
◉	Heimlich manoeuvre ✓ Correct
○	High flow oxygen
○	Removal with forceps

A finger sweep is more likely to push the obstruction further into the airway and is no longer advocated.

High flow oxygen is the breathing part of A, B, C, and the airway is not clear.

Nasopharyngeal airways will not help in this situation.

Removal with forceps is potentially hazardous.

A Heimlich manoeuvre should be performed with the possibility of cricothyroidotomy in mind immediately thereafter if this procedure fails.

depression inferolaterally.

Which of the following would be the most appropriate treatment option for this patient?

(Please select 1 option)

○	IV diamorphine 10 mg
○	Oral aspirin 600 mg
○	Oral isosorbide mononitrate 30 mg
◉	Oxygen 100% ✕ Incorrect answer selected
○	Subcutaneous low molecular weight heparin ← This is the correct answer

The treatment approach in this patient with acute coronary syndrome is

1. aspirin 300 mg
2. try some GTN.

If this fails then

- isosorbitdinitrate (ISDN) intravenously
- diamorphine (or morphine) 2.5 mg
- 4 L oxygen and
- subcutaneous low molecular weight heparin.

A 59-year-old man is admitted with chest pain of eight hours duration and has ST elevation in the inferior leads on his admission ECG.

An electrocardiogram from a previous clinic visit shows sinus rhythm two months ago. He has insulin-dependent diabetes mellitus and chronic renal failure.

Investigations reveal:

Fasting plasma glucose	7.4 mmol/l	(3.0-6.0)
Sodium	137 mmol/l	(137-144)
Potassium	4.4 mmol/l	(3.5-4.9)
Urea	10 mmol/l	(2.5-7.5)
Creatinine	200 µmol/l	(60-110)

Which of the following which represent an absolute contraindication to the use of thrombolysis?

(Please select 1 option)

- Allergy to penicillin
- Gastro intestinal bleeding in last three months
- History of haemorrhagic stroke
- Ischaemic stroke 12 months ago
- On warfarin therapy

Submit answer | Skip question | Tag Question | Remove question

Which of the following which represent an absolute contraindication to the use of thrombolysis?

(Please select 1 option)

○	Allergy to penicillin
○	Gastro intestinal bleeding in last three months
◉	History of haemorrhagic stroke ✓ Correct
○	Ischaemic stroke 12 months ago
○	On warfarin therapy

Absolute contraindications to thrombolysis include:

- Previous haemorrhagic stroke
- Ischaemic stroke in last six months
- Central nervous system damage or neoplasm
- Within three weeks of major surgery, head injury or major trauma
- Active internal bleeding (menses excluded) or gastro-intestinal bleeding within the past month
- Known or suspected aortic dissection
- Known bleeding disorder
- Proliferative diabetic retinopathy.

Allergy and oral anticoagulants are relative contraindications.

Work Smart Session - MRCP Part 1

Time taken: 59 mins 46 secs

Question: 24 of 100

A 67-year-old female is admitted with blackouts.

Her electrocardiogram shows ventricular escape with complete heart block. As you are standing there she blacks out once more. Her rhythm strip shows P wave asystole.

Which of the following would be the initial immediate treatment here after airway and breathing?

(Please select 1 option)

- Adenosine 6 mg
- Atropine 0.6 mg
- Percussion pacing
- Transcutaneous pacing
- Transvenous pacing

Submit answer | Skip question | Remove Tag | Remove question

A 67-year-old female is admitted with blackouts.

Her electrocardiogram shows ventricular escape with complete heart block. As you are standing there she blacks out once more. Her rhythm strip shows P wave asystole.

Which of the following would be the initial immediate treatment here after airway and breathing?

(Please select 1 option)

○	Adenosine 6 mg
○	Atropine 0.6 mg
◉	Percussion pacing ✓ Correct
○	Transcutaneous pacing
○	Transvenous pacing

Adenosine and atropine are not front line agents in this scenario, particularly adenosine which blocks atrioventricular (AV) conduction; minus one mark if you elected this.

Transvenous pacing is not a fast enough intervention here.

Transcutaneous pacing is the immediate management but percussion pacing may be effective as a holding measure whilst this is instituted.

(Percussion pacing involves gentle thumping of the lower left sternal edge with the fist.)

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 53 secs

Question: 25 of 100

A 70-year-old male presents with haematemesis and melaena.

His presenting blood pressure is 80/46 mmHg, with a heart rate of 114 bpm. He is known to have idiopathic cirrhosis, and there is mild encephalopathy.

You fluid resuscitate him with colloid, blood, FFP and dextrose.

Which of the following is the next best step in management?

(Please select 1 option)

○	Ciproflaxacin
○	Glypressin
○	Lactulose
○	OGD
○	Oral beta-blockers

Submit answer | Skip question | Tag Question | Remove question

Which of the following is the next best step in management?

(Please select 1 option)

○	Ciproflaxacin
◉	Glypressin ✓ Correct
○	Lactulose
○	OGD
○	Oral beta-blockers

Glypressin causes splanchnic vasoconstriction, thereby restricting bleeding from varices, which is the likely cause of bleeding in this patient.

In the acute gastrointestinal bleed described above, glypressin is the best treatment to aid cardiovascular resuscitation.

Beta-blockade comes into play later in order to treat portal hypertension chronically.

Lactulose should be considered to guard against progression of encephalopathy.

Oesophagogastroduodenoscopy (OGD) should be considered, but full resuscitation and optimal medical management should be attempted in the first instance.

In the event of ascites, ciprofloxacin is used as prophylaxis against spontaneous bacterial peritonitis. This is of secondary importance here.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 2 mins 2 secs

Question: 26 of 100

A 43-year-old gentleman develops chest pain seven minutes after fibre-optic bronchoscopy.

The procedure had been performed without sedation following an intratracheal injection of 5 ml 2.5% cocaine solution and xylocaine spray to the pharynx for topical anaesthesia.

ECG showed an evolving anterior myocardial infarction.

Which of the following would you prefer for his management?

(Please select 1 option)

- Beta-blockers
- Nitrates
- Percutaneous transluminal coronary angioplasty
- Thrombolysis with rt-PA
- Thrombolysis with streptokinase

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

○	Beta-blockers
◉	Nitrates ✓ Correct
○	Percutaneous transluminal coronary angioplasty
○	Thrombolysis with rt-PA
○	Thrombolysis with streptokinase

The underlying mechanism here is vasoconstriction, not thrombosis.

Cocaine is cardiotoxic and its use has been linked to:

- coronary artery spasm
- angina
- myocardial infarction
- arrhythmias
- sudden cardiac death
- myocardial contraction bands, which might act as a substrate for arrhythmias.

It is important to avoid beta-blockers in treating cocaine-induced chest pains or acute myocardial infarctions, as this may result in unopposed 1 adrenergic action with worsening coronary spasm.

Calcium channel antagonists or nitrates should be administered as early as possible.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 3 mins 20 secs

Question: 27 of 100

A 45-year-old man is admitted with central crushing chest pain, sweating and vomiting of one hour duration.

He is conscious with a pulse rate of 100 bpm and a blood pressure of 200/125 mmHg. An ECG shows >2 mm ST elevation in leads I, II, aVL and V2-6.

CBC: normal
U & E: normal
Troponin T: 100 ng/ml

Apart from the presence of xanthelasma (+) there are no other positive findings on clinical examination.

He is given oxygen, aspirin, morphine and intravenous 5 mg atenolol.

What will you do next?

(Please select 1 option)

○	CABG
○	Nitroprusside infusion
○	PTCA
○	Thrombolysis with rt-PA
○	Thrombolysis with streptokinase

Submit answer | Skip question | Tag Question | Remove question

CBC: normal
U & E: normal
Troponin T: 100 ng/ml

Apart from the presence of xanthelasma (+) there are no other positive findings on clinical examination.

He is given oxygen, aspirin, morphine and intravenous 5 mg atenolol.

What will you do next?

(Please select 1 option)

○	CABG
○	Nitroprusside infusion
◉	PTCA ✓ Correct
○	Thrombolysis with rt-PA
○	Thrombolysis with streptokinase

This is a case of acute myocardial infarction.

Typically thrombolysis should be carried out in the absence of any contraindications. BP higher than 200/120 mmHg is one of the contraindications.

So the next appropriate management in this case is urgent angioplasty for extensive anterolateral infarction.

BP control should follow suit.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 4 mins 47 secs

Question: 28 of 100

A 19-year-old girl has been brought to the Emergency Department by her friends following a night out at a party.

Her friends comment that she has been talking by herself about 'irrelevant things'. She seems agitated and restless.

On examination, her reflexes are increased and an electrocardiogram (ECG) demonstrates ventricular ectopics.

What kind of substance abuse do you suspect at this point?

(Please select 1 option)

- Alcohol
- Barbiturate
- Cannabis
- Ecstasy
- Glue sniffing

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

http://my.onexamination.com/Assessment/Que
Questions Set : REF20333

○	Alcohol
○	Barbiturate
◉	Cannabis ✕ Incorrect answer selected
○	Ecstasy ← This is the correct answer
○	Glue sniffing

This is a case of ecstasy overdose.

Ecstasy (3,4-methylenedioxymethamphetamine, MDMA) stimulates the central nervous system. It causes:

- Increased alertness and self-confidence
- Euphoria
- Extrovert behaviour
- Increased talkativeness with rapid speech
- Lack of desire to eat or sleep
- Tremor
- Dilated pupils
- Tachycardia
- Hypertension.

More severe intoxication is associated with:

- Excitability
- Agitation
- Paranoid delusions
- Hallucinations with violent behaviour

Hypertension.

More severe intoxication is associated with:

- Excitability
- Agitation
- Paranoid delusions
- Hallucinations with violent behaviour
- Hypertonia
- Hyperreflexia.

Convulsions, rhabdomyolysis, hyperthermia, and cardiac arrhythmias may also develop.

In severe cases of MDMA poisoning:

- Hyperthermia
- Disseminated intravascular coagulation
- Rhabdomyolysis
- Acute renal failure
- Hyponatraemia

are observed.

Hepatic damage has also been reported.

Rarely, poisoning due to amphetamines may result in intracerebral and subarachnoid haemorrhage and acute cardiomyopathy; these complications may be fatal.

Hyperthyroxinaemia may be found in chronic amphetamine users.

Question: 29 of 100

A known case of chronic obstructive pulmonary disease (COPD) presents to the Emergency Department, distressed and cyanosed.

Arterial blood gases reveal:

pH	7.2	(7.36-7.44)
PaO_2	8.3 kPa	(11.3-12.6 kPa)
$PaCO_2$	10 kPa	(4.7-6.0 kPa)

He is given high concentration oxygen together with a salbutamol nebuliser. Intravenous hydrocortisone is also given.

The patient becomes even worse with poorer breathing effort although pulse oximetry showed SaO_2 of 93%.

What is the cause of patient's deterioration?

(Please select 1 option)

- Constriction of bronchioles in response to salbutamol nebuliser
- High concentration oxygen administration
- Pulmonary artery relaxation causing mismatch between perfusion and ventilation
- Pulmonary vein relaxation causing mismatch between perfusion and ventilation
- Reaction to IV hydrocortisone

Submit answer | Skip question | Tag Question | Remove question

pH	7.2	(7.36-7.44)
PaO_2	8.3 kPa	(11.3-12.6 kPa)
$PaCO_2$	10 kPa	(4.7-6.0 kPa)

He is given high concentration oxygen together with a salbutamol nebuliser. Intravenous hydrocortisone is also given.

The patient becomes even worse with poorer breathing effort although pulse oximetry showed SaO_2 of 93%.

What is the cause of patient's deterioration?

(Please select 1 option)

- ○ Constriction of bronchioles in response to salbutamol nebuliser
- ◉ High concentration oxygen administration ✓ Correct
- ○ Pulmonary artery relaxation causing mismatch between perfusion and ventilation
- ○ Pulmonary vein relaxation causing mismatch between perfusion and ventilation
- ○ Reaction to IV hydrocortisone

Obviously the patient was suffering from hypoxia and hypercapnia as a result of acute exacerbation of COPD.

His respiratory centre was solely stimulated by hypoxia. That is why his respiratory effort became less and the condition worsened when he was given high concentration oxygen, depriving him of hypoxic drive.

Plasma glucose	6.4 mmol/l	(3.0-6.0)

What is the most likely diagnosis?

(Please select 1 option)

○	Bacterial meningitis
○	Cryptococcal meningitis
○	Tuberculosis meningitis
○	Viral encephalitis
◉	Viral meningitis ✓ Correct

A normal cerbrospinal fluid (CSF) glucose together with

- A CSF lymphocytosis
- An increased opening pressure, and
- A raised CSF protein

are typical of a viral meningitis, which would be high on the list of differentials in patients of this age group (together with bacterial meningitis).

Work Smart Session - MRCP Part 1

Time taken: 6 mins 14 secs

Question: 3 of 100

A 16-year-old female attends casualty 15 hours after ingesting approximately 30 g of paracetamol and 2 g of dihydrocodeine.

On examination, she is drowsy with a Glasgow coma scale of 15. Her pulse is 100 beats per minute, blood pressure is 110/66 mmHg and she has pinpoint pupils, with saturations of 96% on air.

What is the most appropriate treatment for this patient?

(Please select 1 option)

- 10% Dextrose infusion
- Activated charcoal by mouth
- Gastric lavage
- N-acetylcysteine intravenously
- Naloxone intravenously

Submit answer | Skip question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 8 mins 7 secs

Question: 30 of 100

A 52-year-old schoolteacher attends with weight loss and sweats.

She is clinically thyrotoxic with a diffuse goitre.

Subsequent investigations show:

Free T4	40 pmol/l	(9-23)
Free T3	9.8 nmol/l	(3.5-6)
TSH	6.1 mU/l	(0.5-5)

A repeat TFT is similar.

What is the most appropriate investigation for this patient?

(Please select 1 option)

- FNA of thyroid gland
- MRI scan pituitary gland
- Radio-isotope uptake scan of thyroid gland
- Repeat TFT checking for antibody interference
- Thyroid auto antibodies

Submit answer | Skip question | Tag Question | Remove question

Free T4	40 pmol/l	(9-23)
Free T3	9.8 nmol/l	(3.5-6)
TSH	6.1 mU/l	(0.5-5)

A repeat TFT is similar.

What is the most appropriate investigation for this patient?

(Please select 1 option)

- ○ FNA of thyroid gland
- ◉ MRI scan pituitary gland ✓ Correct
- ○ Radio-isotope uptake scan of thyroid gland
- ○ Repeat TFT checking for antibody interference
- ○ Thyroid auto antibodies

This patient is thyrotoxic; however, as the non-suppressed thyroid-stimulating hormone (TSH) suggests that this is due to excessive TSH production by the pituitary gland, the possibility of a thyrotroph adenoma must be pursued.

In primary hyperthyroidism the TSH should always be suppressed by negative feedback, which is not the case here.

TSH-omas are indeed very rare, but the giveaway would be the normal or elevated TSH with thyrotoxicosis.

Question: 31 of 100

A 27-year-old female presents to the surgical intake with abdominal pain and a five day history of vomiting.

Over the last three months she has also been aware of a 6 kg weight loss.

On examination, she is pale, has a temperature of 38.5°C, blood pressure of 90/60 mmHg and pulse rate of 130 in sinus rhythm. The chest is clear on auscultation but she has a diffusely tender abdomen with no guarding. Her BM reading is 2.5.

Initial biochemistry is as follows:

Sodium	124 mmol/l	(137-144)
Potassium	6.0 mmol/l	(3.5-4.9)
Urea	7.5 mmol/l	(2.5-7.5)
Creatinine	78 µmol/l	(60-110)
Glucose	2.0 mmol/l	(3.0-6.0)

What is the probable diagnosis?

(Please select 1 option)

- ○ Abdominal migraine
- ○ Acute appendicitis
- ○ Acute cholecystitis
- ○ Addison's disease
- ○ Insulinoma

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Sodium	124 mmol/l	(137-144)
Potassium	6.0 mmol/l	(3.5-4.9)
Urea	7.5 mmol/l	(2.5-7.5)
Creatinine	78 µmol/l	(60-110)
Glucose	2.0 mmol/l	(3.0-6.0)

What is the probable diagnosis?

(Please select 1 option)

- ○ Abdominal migraine
- ○ Acute appendicitis
- ○ Acute cholecystitis
- ◉ Addison's disease ✓ Correct
- ○ Insulinoma

This patient has clinical features of hypoadrenal crisis with abdominal pain and vomiting and shock with hypoglycaemia, hyponatraemia and hyperkalaemia in keeping with hypoadrenalism.

She needs emergency fluid resuscitation, steroid administration (prior to this urgent cortisol measurement), and careful search for occult infection.

One may expect to find features of Addison's disease such as oral pigmentation or other autoimmune disease.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 13 mins 11 secs

Question: 32 of 100

A 78-year-old male is brought to the Emergency Department and has a witnessed seizure in the resuscitation room.

His blood glucose is recorded as 1.0 mmol/l. He does not have diabetes, and has no other significant past medical history.

He is given 50 ml of 50% dextrose and he slowly recovers over the next one hour. A serum cortisol concentration later returns as 800 nmol/l (120-600).

Which of the following would be the most relevant investigation for this man?

(Please select 1 option)

○	Chest x ray
○	CT head scan
○	Electrocardiogram
◉	Prolonged 72 hour fast
○	Short synacthen test

Submit answer | Skip question | Tag Question | Remove question

He is given 50 ml of 50% dextrose and he slowly recovers over the next one hour. A serum cortisol concentration later returns as 800 nmol/l (120-600).

Which of the following would be the most relevant investigation for this man?

(Please select 1 option)

○	Chest x ray
○	CT head scan
○	Electrocardiogram
◉	Prolonged 72 hour fast ✓ Correct
○	Short synacthen test

The historical and biochemical evidence here suggests a diagnosis of spontaneous hypoglycaemia, and the most likely cause would be an insulinoma. However, one would wish to exclude possible drug administration and although not mentioned here, a sulphonylurea screen should be undertaken.

He has presented with symptomatic hypoglycaemia, is not diabetic and therefore should not have received insulin or a sulphonylurea.

There is nothing to suggest alcohol or drug misuse. Similarly, there is nothing to suggest sepsis.

However, to prove a diagnosis of spontaneous hypoglycaemia, a prolonged fast is required and should he develop hypoglycaemia, measurement of insulin and C-peptide will be needed to confirm the diagnosis.

The appropriate cortisol response during his hypoglycaemic episode (cortisol 800) excludes hypoadrenalism.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 17 mins 22 secs

Question: 33 of 100

A 65-year-old man is admitted from home with a community-acquired pneumonia (CAP). He has a history of skin rash to penicillin documented in his medical notes. He has adverse prognostic features and a CURB score of 4.

What would be an appropriate empirical antibiotic choice?

(Please select 1 option)

- Augmentin and clarithromycin
- Augmentin and gentamycin
- Cefotaxime and erythromycin
- Cefuroxime and metronidazole
- Ciprofloxacin and clarithromycin

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Question: 33 of 100

A 65-year-old man is admitted from home with a community-acquired pneumonia (CAP). He has a history of skin rash to penicillin documented in his medical notes. He has adverse prognostic features and a CURB score of 4.

What would be an appropriate empirical antibiotic choice?

(Please select 1 option)

○	Augmentin and clarithromycin
○	Augmentin and gentamycin
◉	Cefotaxime and erythromycin ✓ Correct
○	Cefuroxime and metronidazole
○	Ciprofloxacin and clarithromycin

Community-acquired pneumonia is most commonly caused by *Strep. pneumoniae*, hence the use of a beta-lactam antibiotic because of the increased incidence of atypical organisms such as mycoplasma. A macrolide such as erythromycin is also recommended.

Augmentin is contraindicated as it is penicillin-based.

Ciprofloxacin has poor cover against *Strep. pneumoniae* and metronidazole is used for anaerobic infections.

In this case a credible alternative for beta-lactam sensitivity is not mentioned and the best choice, because of clinical necessity since severe pneumonia can be fatal if treated with antibiotics that are not effective, is to go with the only cephalosporin and macrolide combination that is offered.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 52 mins 9 secs

Question: 34 of 100

A 38-year-old man experiences sudden deterioration after being admitted to the intensive care unit because of severe pneumococcal pneumonia and septic shock.

Arterial blood gas analysis reveals:

pH	7.2	(7.36-7.44)
PaO_2	12 kPa	(10-13.3)
$PaCO_2$	4.7 kPa	(4.7-6)
HCO_3^-	16 mmol/l	(20-28)

Which one of the following changes will be found in this patient at this time?

(Please select 1 option)

- Hyperventilation leading to the increase in CO_2 concentration
- Increase production of HCO_3-
- Increased renal excretion of HCO_3-
- Raised hydrogen ions level in the blood
- Respiratory acidosis

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 58 mins 48 secs

Question: 35 of 100

A 53-year-old man with a known history of Graves' disease presents to the emergency department with palpitations, anxiety and fine tremor of both hands.

ECG shows rapid atrial fibrillation (AF) with ventricular rate of 160 to 180/min.

His blood pressure was 110/80 mmHg.

TSH	0.01 mU/l	(0.4-5.0)
Free T4	60.3 pmol/l	(10-22)

What is the immediate management for this patient?

(Please select 1 option)

- Carbimazole
- DC cardioversion
- Digoxin
- Propanolol
- Warfarin

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 5 mins 26 secs

Question: 36 of 100

A middle-aged woman presents with new onset palpitations. She also commented that she had lost weight recently despite an increased appetite.

Examination reveals a goitre and a degree of exophthalmos. During physical examination, she fell unconscious. Blood pressure was 70/40 mmHg. Electrocardiogram revealed atrial fibrillation (AF) with rapid ventricular response.

What is the appropriate immediate management?

(Please select 1 option)

- Anticoagulation
- Carbimazole
- DC cardioversion
- Intravenous amiodarone
- Intravenous propanolol

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Examination reveals a goitre and a degree of exophthalmos. During physical examination, she fell unconscious. Blood pressure was 70/40 mmHg. Electrocardiogram revealed atrial fibrillation (AF) with rapid ventricular response.

What is the appropriate immediate management?

(Please select 1 option)

○	Anticoagulation
○	Carbimazole
◉	DC cardioversion ✓ Correct
○	Intravenous amiodarone
○	Intravenous propanolol

The patient is haemodynamically compromised due to AF.

The emergency management is DC cardioversion 200 J ⇒ 360 J ⇒ 360 J.

Adverse signs necessitating DC cardioversion are:

- BP ≤90 mmHg
- chest pain
- heart failure
- impaired consciousness
- heart rate ≥200 bpm.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 6 mins 38 secs

Question: 37 of 100

A 41-year-old female is brought into the Emergency Department after taking an uncertain quantity of paracetamol two hours previously and trying to hang herself.

She becomes agitated and insists that she wants to go home immediately. You judge that she is at high risk of suicide.

Which of the following is the most appropriate course of action for this patient?

(Please select 1 option)

- Ask her to sign a 'discharge against medical advice' form and let her go
- Call the duty psychiatrist, and with other staff in the Emergency Department attempt to restrain her under common law until they arrive
- Call the duty psychiatrist, but let the patient go if she insists and the duty psychiatrist does not arrive in time to see her
- Call the hospital security services, restrain her and sedate her
- Detain her under section 5(2) of the Mental Health Act

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 41-year-old female is brought into the Emergency Department after taking an uncertain quantity of paracetamol two hours previously and trying to hang herself.

She becomes agitated and insists that she wants to go home immediately. You judge that she is at high risk of suicide.

Which of the following is the most appropriate course of action for this patient?

(Please select 1 option)

○	Ask her to sign a 'discharge against medical advice' form and let her go
○	Call the duty psychiatrist, and with other staff in the Emergency Department attempt to restrain her under common law until they arrive ← This is the correct answer
○	Call the duty psychiatrist, but let the patient go if she insists and the duty psychiatrist does not arrive in time to see her
◉	Call the hospital security services, restrain her and sedate her ✕ Incorrect answer selected
○	Detain her under section 5(2) of the Mental Health Act

In an Emergency Department the suicidal patient who declines to be admitted for observation and treatment should be managed as follows:

- Ensure that a member of staff stays with them at all times
- Call the duty psychiatrist if they attempt to abscond before or during psychiatric assessment.

The staff of the Emergency Department have a duty under common law to restrain the patient.

If a patient who is already being nursed on a medical, surgical or obstetric ward, or in a high dependency or intensive care unit, develops a mental illness (or has an exacerbation of a pre-existing disorder), their physician or surgeon can authorise their compulsory detention for up to 72 hours under section 5(2) of the Mental Health Act.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 8 mins 46 secs

Question: 38 of 100

A 65-year-old male is admitted with a two hour history of central chest pain associated with sweating and nausea. A myocardial infarction is suspected.

Which of the following is an indication for thrombolytic therapy?

(Please select 1 option)

- 1 mm ST elevation in leads II, III and aVF
- 1 mm ST elevation in leads V2 and V6
- 2 mm ST depression in leads V2-4
- Q waves in leads V2-4
- T wave inversion in lead V3-5

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 10 mins 28 secs

Question: 38 of 100

A 65-year-old male is admitted with a two hour history of central chest pain associated with sweating and nausea. A myocardial infarction is suspected.

Which of the following is an indication for thrombolytic therapy?

(Please select 1 option)

○	1 mm ST elevation in leads II, III and aVF ← This is the correct answer
◉	1 mm ST elevation in leads V2 and V6 ✕ Incorrect answer selected
○	2 mm ST depression in leads V2-4
○	Q waves in leads V2-4
○	T wave inversion in lead V3-5

There are two electrocardiogram (ECG) criteria for initiating thrombolysis in a patient with suspected myocardial infarction.

The first is the presence of ST elevation of at least 1 mm in the limb leads or 1 mm in contiguous chest leads on the ECG.

The second is new onset of left bundle branch block (LBBB.)

Also, there must be no compelling contra-indications to thrombolysis.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 10 mins 28 secs

Question: 39 of 100

A 45-year-old male with a long history of alcohol abuse presents with a two day history of deteriorating confusion.

On examination he is drowsy, has a temperature of 39°C, a pulse of 110 beats per minute, a small amount of ascites and has features of a left side hemiparesis.

What is the most likely diagnosis?

(Please select 1 option)

- Cerebral abscess
- Cerebro-vascular accident (CVA)
- Hepatic encephalopathy
- Subdural haematoma
- Wernicke's encephalopathy

Question: 39 of 100

A 45-year-old male with a long history of alcohol abuse presents with a two day history of deteriorating confusion.

On examination he is drowsy, has a temperature of 39°C, a pulse of 110 beats per minute, a small amount of ascites and has features of a left side hemiparesis.

What is the most likely diagnosis?

(Please select 1 option)

◉	Cerebral abscess ✓ Correct
○	Cerebro-vascular accident (CVA)
○	Hepatic encephalopathy
○	Subdural haematoma
○	Wernicke's encephalopathy

This man with chronic alcohol abuse now presents with a fever and left hemiparesis.

The most likely diagnosis would therefore be cerebral abscess.

The fever would not itself be explained by a subdural haematoma nor would a simple CVA explain this.

Similarly, delirium tremens or encephalopathy would not be associated with the hemiparesis.

Next question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

On examination, she is drowsy with a Glasgow coma scale of 15. Her pulse is 100 beats per minute, blood pressure is 110/66 mmHg and she has pinpoint pupils, with saturations of 96% on air.

What is the most appropriate treatment for this patient?

(Please select 1 option)

○	10% Dextrose infusion
○	Activated charcoal by mouth
○	Gastric lavage
◉	N-acetylcysteine intravenously ✓ Correct
○	Naloxone intravenously

This patient has taken a significant overdose of paracetamol, and is presenting late at 15 hours.

She is at risk of hepatocellular damage and needs to be commenced on an infusion of intravenous N-acetylcysteine immediately. It is continued for 30 hours and sometimes beyond this, depending on results of prothrombin time, liver function tests, urea and electrolytes, and glucose.

Activated charcoal is given to patients presenting within one hour of overdose.

Flumazenil is reserved for reversal of benzodiazepine-induced respiratory depression.

Naloxone is used for opiate-induced respiratory depression.

Work Smart Session - MRCP Part 1

Time taken: 11 mins 5 secs

Question: 4 of 100

A 35-year-old business man presents with anxiety and palpitations after 'snorting' cocaine. The patient denies any prior use and has also consumed some alcohol.

On examination, he is distressed and sweating with a temperature of 38°C, pulse of 138 beats per minute (regular) and a blood pressure of 216/110 mmHg. His ECG reveals a sinus tachycardia.

Which of the following is the most appropriate initial treatment for this man?

(Please select 1 option)

- Dantrolene
- Diazepam
- Lidocaine
- Propranolol
- Verapamil

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 13 mins 12 secs

Question: 40 of 100

A 19-year-old female with type 1 diabetes is admitted with diabetic ketoacidosis.

Which of the following is most appropriate concerning the use of a bicarbonate infusion?

(Please select 1 option)

○	Bicarbonate infusion should be considered at pH less than 7
○	Commence a bicarbonate infusion with a ketone concentration above 5 mmol/l (NR les than 1)
○	Commence bicarbonate infusion with a potassium concentration above 6 mmol/l
○	Commence a bicarbonate infusion with a standard bicarbonate concentration below 5 mmol/l (NR 22-26)
○	No benefit from using a bicarbonate infusion

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 15 mins 5 secs

Question: 40 of 100

A 19-year-old female with type 1 diabetes is admitted with diabetic ketoacidosis.

Which of the following is most appropriate concerning the use of a bicarbonate infusion?

(Please select 1 option)

○	Bicarbonate infusion should be considered at pH less than 7 ← This is the correct answer
○	Commence a bicarbonate infusion with a ketone concentration above 5 mmol/l (NR les than 1)
○	Commence bicarbonate infusion with a potassium concentration above 6 mmol/l
○	Commence a bicarbonate infusion with a standard bicarbonate concentration below 5 mmol/l (NR 22-26)
◉	No benefit from using a bicarbonate infusion ✕ Incorrect answer selected

The use of bicarbonate in DKA is controversial (pdf).

However, most authorities agree that a bicarbonate infusion may be used in subjects with a severe metabolic acidosis (pH less than 7).

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 15 mins 5 secs

Question: 41 of 100

A 31-year-old female with pulmonary hypertension complains of increasing shortness of breath. She is 36 weeks gestation in her first pregnancy.

Which of the following statements is correct?

(Please select 1 option)

- Chest x ray is contraindicated
- Elevated D-dimers rule out PE
- Enoxaparin dose should be halved in pregnancy
- Nifedipine is contraindicated in pregnancy
- Risk of maternal mortality in patients with pulmonary hypertension is 30%

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Which of the following statements is correct?

(Please select 1 option)

○	Chest x ray is contraindicated
○	Elevated D-dimers rule out PE
○	Enoxaparin dose should be halved in pregnancy
◉	Nifedipine is contraindicated in pregnancy ✕ Incorrect answer selected
○	Risk of maternal mortality in patients with pulmonary hypertension is 30% ← This is the correct answer

A chest x ray is not contraindicated in pregnancy.

Any pregnant female presenting with shortness of breath should be reviewed by a senior member of the obstetric team, advice which comes from the RCOG.

Enoxaparin dose should be doubled in pregnancy, due to the increased glomerular filtration rate (GFR) in pregnancy.

D-dimers are always elevated in pregnancy, and are not helpful as a diagnostic aid, unless of course they are low (very unlikely), thereby making the clinical suspicion of pulmonary embolism (PE) low.

Nifedipine is not contraindicated in pregnancy, but should be used judiciously.

Labetalol and methyldopa are the commonest antihypertensives used in pregnancy.

Patients with pulmonary hypertension have a high mortality of at least 30% - some authors put it at 50% - seemingly highest immediately after delivery.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 16 mins 48 secs

Question: 42 of 100

A 16-year-old man is brought to the emergency department with a GCS (Glasgow coma scale) rating of 3/15.

Within 10 minutes he regained consciousness with a GCS of 15/15, is sitting up and talking.

What is he likely to have taken?

(Please select 1 option)

- Inhaled solvent glue
- Smoked heroin
- Smoked marijuana
- Snorted cocaine
- Taken ecstacy

Submit answer | Skip question | Tag Question | Remove question

Question: 42 of 100

A 16-year-old man is brought to the emergency department with a GCS (Glasgow coma scale) rating of 3/15.

Within 10 minutes he regained consciousness with a GCS of 15/15, is sitting up and talking.

What is he likely to have taken?

(Please select 1 option)

○	Inhaled solvent glue ← This is the correct answer
◉	Smoked heroin ✕ Incorrect answer selected
○	Smoked marijuana
○	Snorted cocaine
○	Taken ecstacy

This patient was markedly comatose on arrival but quickly regains consciousness. This suggests a short acting (probably) inhaled anaesthetic-like agent - glue.

Marijuana would not be expected to produce this level of coma and the effects of cocaine would last much longer.

The inhaled solvents, due to their lipophilicity, are rapidly absorbed through the lungs and then quickly distributed to the brain and other organs. The effects therefore appear within minutes of inhalation.

Typical substances that are inhaled include toluene aromatic hydrocarbons and butane.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 18 mins 44 secs

Question: 43 of 100

A 21-year-old man, who has a past history of IV drug abuse, presents 12 hours after taking an overdose of 480 mg of codeine and 30 g of paracetamol.

His blood pressure is 100/60 mmHg and he has pin-point pupils.

What is the most appropriate management for this patient?

(Please select 1 option)

- 500ml 10% glucose IV over four hours
- 1 litre normal saline IV over six hours
- IV naloxone
- IV flumazenil
- Start N-acetylcysteine

Submit answer | Skip question | Remove Tag | Remove question

A 21-year-old man, who has a past history of IV drug abuse, presents 12 hours after taking an overdose of 480 mg of codeine and 30 g of paracetamol.

His blood pressure is 100/60 mmHg and he has pin-point pupils.

What is the most appropriate management for this patient?

(Please select 1 option)

○	500ml 10% glucose IV over four hours
○	1 litre normal saline IV over six hours
○	IV naloxone
○	IV flumazenil
◉	Start N-acetylcysteine ✓ Correct

This patient presents 12 hours after taking a potentially fatally toxic dose of paracetamol.

In the circumstances provided in this question where there is an absence of data relating to pulse rate (as he is probably not in shock), respiratory rate (reflecting respiratory depression) or blood glucose, the most appropriate intervention at this 12 hour time-point would be N-acetylcysteine.

The urgency of treatment is underlined by the fact that the incidence of hepatotoxicity is worse if treatment is delayed.

Trials of N-acetylcysteine suggest that the incidence of hepatotoxicity is 1% in those treated within eight hours versus 46% in those treated after 16 hours.

A 51-year-old lady presented to hospital with a two day history of malaise and headache.

On the day of admission the headache had become more intense and was associated with pain in her neck.

Her husband reported that she had also been febrile and confused at times. She had previously been well and had no significant past medical history.

On examination, she was febrile 38.1°C, looked unwell and was photophobic. Kernig's and Brudzinski's signs were positive. The fundi were normal with no evidence of papilloedema.

Following a normal CT scan a lumbar puncture was performed and CSF analysis showed:

White cells	200/mm^3	
Red cells	2/mm^3	
CSF protein	0.9 g/l	(0.15-0.45)
CSF glucose	1.6 mmol/l	(3.3-4.4)
Plasma glucose	5.3 mmol/l	(3.0-6.0)

What is the most likely causative organism?

(Please select 1 option)

- ○ *Eschericia coli*
- ○ *Listeria monocytogenes*
- ○ *Mycobacterium tuberculosis*
- ○ *Streptococcus pneumoniae*
- ○ *Streptococcus pyogenes*

Submit answer | Skip question | Tag Question | Remove question

http://my.onexamination.com/Assessment/Que
Questions Set : REF11185
Intravenous N-acetylcystine: t...

	Mycobacterium tuberculosis
◉	*Streptococcus pneumoniae* ✓ Correct
○	*Streptococcus pyogenes*

The most common causes of bacterial meningitis in persons over 50 years of age are:

1. *Streptococcus pneumoniae*
2. *Neisseria meningitidis*
3. *Listeria monocytogenes*
4. Gram-negative bacilli.

Although this question tries to establish whether candidates are aware of the most common cause of meningitis in this group, some questions in the examination give additional clues as to the cause of meningitis.

Physical examination may provide clues to the aetiology of meningitis in affected patients:

1. Morbilliform rash with pharyngitis and lymphadenopathy may suggest a viral aetiology (Epstein-Barr virus [EBV], cytomegalovirus [CMV], adenovirus, human immunodeficiency virus [HIV]).
2. Macules and petechiae that rapidly evolve into purpura suggest meningococcaemia (with or without meningitis).
3. Vesicular lesions in a dermatomal distribution suggest *Varicella zoster* virus.
4. Genital vesicles suggest *Herpes simplex* virus (HSV)-2 meningitis.
5. Sinusitis or otitis suggest direct extension into the meninges, usually with *Streptococcus pneumoniae* and *Haemophilus influenzae*.
6. Rhinorrhea or otorrhea suggest a cerebrospinal fluid (CSF) leak from a basilar skull fracture, with meningitis most commonly caused by *Streptococcus pneumoniae*.
7. Hepatosplenomegaly and lymphadenopathy suggest a systemic disease, including viral (for example, mononucleosis-like syndrome in EBV, CMV, and HIV) and fungal (for example, disseminated histoplasmosis) disease.
8. The presence of a murmur suggests infective endocarditis with secondary bacterial seeding of the meninges.
9. Evidence of parotitis is observed in some cases of mumps meningitis.

Kernig's sign (pdf)
In a supine patient, flex the hip to 90° while the knee is flexed at 90°. An attempt to further extend the knee produces pain in the hamstrings and resistance to further extension.

Brudzinski's sign (pdf)

2. *Neisseria meningitidis*
3. *Listeria monocytogenes*
4. Gram-negative bacilli.

Although this question tries to establish whether candidates are aware of the most common cause of meningitis in this group, some questions in the examination give additional clues as to the cause of meningitis.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 23 mins 34 secs

Question: 45 of 100

An anxious 22-year-old female with a high respiration rate has the following arterial blood gas results:

pH	7.27	(7.36-7.44)
PCO_2	2.6KPa	(4.7-6.0)
Base deficit	12 mmol/l	

What is the interpretation of the acid-base status?

(Please select 1 option)

- Combined metabolic and respiratory acidosis
- Combined metabolic and respiratory alkalosis
- Metabolic acidosis with some compensatory respiratory alkalosis
- Respiratory acidosis with some compensatory metabolic alkalosis
- Respiratory alkalosis with some compensatory metabolic acidosis

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

An anxious 22-year-old female with a high respiration rate has the following arterial blood gas results:

pH	7.27	(7.36-7.44)
PCO_2	2.6KPa	(4.7-6.0)
Base deficit	12 mmol/l	

What is the interpretation of the acid-base status?

(Please select 1 option)

- Combined metabolic and respiratory acidosis
- Combined metabolic and respiratory alkalosis
- Metabolic acidosis with some compensatory respiratory alkalosis ← This is the correct answer
- Respiratory acidosis with some compensatory metabolic alkalosis
- (●) Respiratory alkalosis with some compensatory metabolic acidosis ✕ Incorrect answer selected

This patient has a metabolic acidosis as evidenced by a pH of 7.27 and a base deficit, which is a marker of the extent of acidosis.

The low CO_2 is a reflection of the physiological respiratory compensation which is attempting to normalise pH by clearing the acidic gas CO_2.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 26 mins 53 secs

Question: 46 of 100

A 22-year-old female develops a wheeze and extensive rash whilst eating a Chinese take-away.

On examination, she has extensive wheeze and stridor, with urticaria covering her upper and lower limbs and trunk. Her BP is 80/45 mmHg.

What is the likely diagnosis?

(Please select 1 option)

- C1 esterase deficiency
- Food poisoning
- Idiopathic urticaria
- Monosodium glutamate syndrome
- Peanut allergy

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

C1 esterase deficiency

Food poisoning

Idiopathic urticaria

Monosodium glutamate syndrome

Peanut allergy ✓ Correct

Chinese cooking uses cashew nuts in many dishes, and patients with peanut allergy may also experience an anaphylactic reaction with cashew nuts. Chinese chefs also use peanut oil in the stir fry, and this may also precipitate an allergic reaction.

An acute hypersensitivity reaction to monosodium glutamate (MSG) a preservative common in Chinese food, may give rise to the 'MSG syndrome'. This is characterised by

- a sudden onset of headache
- heartburn
- palpitations
- sweating
- swelling
- flushing of the face.

Patients may report a sense of increased facial pressure or tingling in the face. Symptoms generally start within two hours of eating foods rich in MSG. This condition is generally self-limited and will resolve. Antihistamines can be helpful in some cases.

It is extremely unlikely that this syndrome will cause shock, which is what this patient presents with given the hypotension.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 28 mins 34 secs

Question: 47 of 100

A 18-year-old female is brought to the Emergency Department unconscious after having taken an overdose.

On examination she has a Glasgow coma score of 6, a respiratory rate of eight breaths per minute, a heart rate of 52 beats per minute and her blood pressure is 84/62 mmHg. Her pupils are small but are reactive to light, muscle tone is reduced and plantar responses are flexor.

Which of the following is she most likely to have taken in overdose?

(Please select 1 option)

○	Diazepam
○	Dihydrocodeine
○	Diphenhydramine
○	Ecstasy (MDMA)
○	Methanol

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

On examination she has a Glasgow coma score of 6, a respiratory rate of eight breaths per minute, a heart rate of 52 beats per minute and her blood pressure is 84/62 mmHg. Her pupils are small but are reactive to light, muscle tone is reduced and plantar responses are flexor.

Which of the following is she most likely to have taken in overdose?

(Please select 1 option)

○	Diazepam
◉	Dihydrocodeine ✓ Correct
○	Diphenhydramine
○	Ecstasy (MDMA)
○	Methanol

Dihydrocodeine is an opiate analgesic and when taken in overdose has a number of toxic effects. It acts as a respiratory depressant leading to reduced respiratory rate. It can cause bradycardia and hypotension in large doses. Pupillary constriction is a diagnostic feature in opiate overdose.

It is also a central nervous system (CNS) depressant and therefore causes coma in overdose.

Benzodiazepines and antihistamines tend not to have the same cardiorespiratory effects as opiates.

MDMA is a stimulant and can cause delirium, convulsions and ventricular arrhythmias.

Diazepam would be less likely here due to the bradycardia and the hypotension.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 30 mins 34 secs

Question: 48 of 100

A 17-year-old male presents to the Emergency Department after an overdose of alcohol and paracetamol.

He complained of abdominal discomfort and an intravenous infusion of N-acetylcysteine was commenced. 15 minutes later he developed breathlessness, reported feeling flushed and developed a tachycardia.

Which of the following is most likely to have occurred?

(Please select 1 option)

- A disulfiram-like (antabuse) reaction has occurred
- The patient has developed pulmonary oedema
- The patient has had a panic attack
- The patient has received an overdose of N-acetylcysteine
- The patient has received N-acetylcysteine previously

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 33 mins 19 secs

Question: 49 of 100

A 55-year-old homeless male was found stuporous and smelling of alcohol.

Observations in the emergency department reveal a core temperature of 34°C, a pulse of 50 bpm and blood pressure of 116/80 mmHg. Dipstick urine analysis shows blood +++.

Some of his investigations are listed:

Creatinine	320 µmol/l	(60-110)
Gamma GT	40 U/l	(10-40)
AST	550 U/l	(1-40)
LDH	1500 U/l	(10-250)

Urine microscopy no cells or organisms.

What is the most likely cause of the raised serum creatinine concentration?

(Please select 1 option)

- ○ Chronic renal failure
- ○ Dehydration
- ○ Hypothermia
- ○ Paracetamol poisoning
- ○ Rhabdomyolysis

LDH	1500 U/l	(10-250)

Urine microscopy no cells or organisms.

What is the most likely cause of the raised serum creatinine concentration?

(Please select 1 option)

- ○ Chronic renal failure
- ○ Dehydration
- ○ Hypothermia
- ○ Paracetamol poisoning
- ◉ Rhabdomyolysis ✓ Correct

The elevated serum creatinine is most likely due to rhabdomyolysis as the patient was found unconscious, is hypothermic, and is likely to have sustained muscle injury.

The latter is confirmed by an elevated aspartate aminotransferase and lactate dehydrogenase (LDH) but the normal gamma-glutamyl transpeptidase (GGT) argues against these being released from the liver.

Rhabdomyolysis is strongly suggested by the fact that urinalysis is strongly positive for blood, whereas urine microscopy is negative for red blood cells.

The positive urinalysis is caused by myoglobin, a muscle protein released during muscle damage; this appears in the urine and can cause acute renal failure.

Which of the following is the most appropriate initial treatment for this man?

(Please select 1 option)

○	Dantrolene
○	Diazepam ← This is the correct answer
○	Lidocaine
◉	Propranolol ✕ Incorrect answer selected
○	Verapamil

Cocaine abuse is quite common and neurological and cardiovascular side effects predominate. Delirium, hyperthermia, dysrrhythmias, as well as myocardial and cerebral infarctions are reported.

In this patient, the first consideration should be attention to airway, breathing and circulation (ABC) and also to remove any residual cocaine from the nares.

Generally, the toxic effects of cocaine are short lived and relate to sympathetic stimulation, in this case with tachycardia, pyrexia and hypertension.

The most appropriate treatment would be an intravenous (IV) benzodiazepine such as diazepam, which relieves the sympathetic adrenergic overdrive and would be expected to relieve these features including the hypertension.

If further treatment is required, IV nitrates can be used and are particularly useful for associated coronary artery spasm.

Beta-blockers should be avoided as they may depress cardiac output, which may exacerbate the depressive effect of cocaine.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 37 mins 28 secs

Question: 50 of 100

A 16-year-old girl presents with an acute exacerbation of asthma.

On examination her respiratory rate was 30 per minute, her heart rate was 120 beats per minute and a peak expiratory flow rate (PEFR) was 30% of the predicted value.

Her blood gas analysis on air shows:

PaO_2	9 kPa	(11.3-12.6)
$PaCO_2$	3.5 kPa	(4.7-6.0)

After the administration of oxygen and corticosteroids what is the most appropriate next step in management?

(Please select 1 option)

- Intravenous aminophylline
- Intravenous salbutamol
- Ipratropium bromide via oxygen-driven nebuliser
- Salbutamol via oxygen-driven nebuliser
- Salmeterol via breath-actuated inhaler

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

On examination her respiratory rate was 30 per minute, her heart rate was 120 beats per minute and a peak expiratory flow rate (PEFR) was 30% of the predicted value.

Her blood gas analysis on air shows:

PaO_2	9 kPa	(11.3-12.6)
$PaCO_2$	3.5 kPa	(4.7-6.0)

After the administration of oxygen and corticosteroids what is the most appropriate next step in management?

(Please select 1 option)

- ○ Intravenous aminophylline
- ○ Intravenous salbutamol
- ○ Ipratropium bromide via oxygen-driven nebuliser
- ◉ Salbutamol via oxygen-driven nebuliser ✓ Correct
- ○ Salmeterol via breath-actuated inhaler

This patient has severe asthma as revealed by the low PEFR, low $P0_2$ and signs.

The next stage in the management is the administration of nebulised beta 2 agonists with supplementation of high flow oxygen (minimum of 6 l/minute). Beta 2 agonists can be administered in 15-30 minute intervals if required.

Intravenous therapy with beta 2 agonists should only be used if inhaled therapies cannot be reliably administered.

Time taken: 2 hrs 39 mins 57 secs

Question: 51 of 100

A 72-year-old man presented following three episodes of transient loss of consciousness not associated with chest pain. There was a previous history of an anterior myocardial infarction.

On examination his blood pressure was 140/80 mmHg and the apex beat was diffuse in character and displaced to the left. There were no neurological signs.

The ECG showed sinus rhythm with occasional ventricular extrasystoles, deep anterior Q waves and ST segment elevation in leads V2 - V6, without reciprocal depression.

Which one of the following would be the most appropriate initial course of action?

(Please select 1 option)

- Administer tissue plasminogen activator
- Arrange an electroencephalogram
- Arrange immediate computerised tomography (CT) brain scan
- Observe in the coronary care unit
- Proceed to coronary arteriography

Submit answer | Skip question | Tag Question | Remove question

On examination his blood pressure was 140/80 mmHg and the apex beat was diffuse in character and displaced to the left. There were no neurological signs.

The ECG showed sinus rhythm with occasional ventricular extrasystoles, deep anterior Q waves and ST segment elevation in leads V2 - V6, without reciprocal depression.

Which one of the following would be the most appropriate initial course of action?

(Please select 1 option)

◉	Administer tissue plasminogen activator ✕ Incorrect answer selected
○	Arrange an electroencephalogram
○	Arrange immediate computerised tomography (CT) brain scan
○	Observe in the coronary care unit ← This is the correct answer
○	Proceed to coronary arteriography

The history suggests that this man has persistent ST elevation in the anterior leads, with a previous history of anterior myocardial infarction due to left ventricular (LV) aneurysm. The blackouts are cardiac syncope due to rhythm disturbance. An ECHO would quickly support the diagnosis but, because of the risk of sudden death, observation on CCU is required.

The loss of consciousness is likely to be due to recurrent arrhythmic episodes or vertebrobasilar transient ischaemic attacks (TIAs), as a result of embolisation of an LV thrombus.

The most important investigation for this patient whom you suspect has arrhythmic episodes would be telemetry/24 hour monitoring, and hence observation on the coronary care unit (CCU) is appropriate.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 16 mins 10 secs

Question: 52 of 100

A 17-year-old woman presented six hours after taking 30 g of paracetamol.

Which of the following factors is most likely to predict an increased risk of hepatotoxicity from the paracetamol?

(Please select 1 option)

- Anorexia nervosa
- Consumption of 20 units of alcohol since taking the paracetamol
- Gilbert's disease
- Ingestion of amitriptyline with the paracetamol
- Smoking 20 cigarettes per day

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 19 mins 33 secs

Question: 52 of 100

A 17-year-old woman presented six hours after taking 30 g of paracetamol.

Which of the following factors is most likely to predict an increased risk of hepatotoxicity from the paracetamol?

(Please select 1 option)

◉	Anorexia nervosa ✓ Correct
○	Consumption of 20 units of alcohol since taking the paracetamol
○	Gilbert's disease
○	Ingestion of amitriptyline with the paracetamol
○	Smoking 20 cigarettes per day

High risk groups in paracetamol overdose include:

- malnourished patients (anorexia nervosa/bulimia nervosa)
- patients taking enzyme inducing drugs (e.g. carbamazepine, phenytoin, rifampicin and St John's wort)
- patients with induced liver enzymes due to chronic ethanol abuse
- human immunodeficiency virus (HIV) positive patients.

See review in *Clinical Medicine* Vol 3 No **2** 2003.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 20 mins 34 secs

Question: 54 of 100

A 30-year-old woman becomes anuric 24 hours after a difficult laparoscopic cholecystectomy.

Investigations reveal:

Serum urea	9.2 mmol/l	(2.5-7.5)
Serum creatinine	120 micro mol/l	(60-110)

The blood pressure is 90/50 mmHg.

What is the next single most appropriate course of action in the management of the anuria?

(Please select 1 option)

- 1 L normal saline intravenously as fast as possible.
- Commence intravenous low-dose dopamine
- Give an 80 mg intravenous bolus of furosemide
- Give 500 ml intravenous plasma expander over 4 hours
- Urgent renal ultrasound

Dashboard
Questions

(Please select 1 option)

◉	1 L normal saline intravenously as fast as possible. ✓ Correct
○	Commence intravenous low-dose dopamine
○	Give an 80 mg intravenous bolus of furosemide
○	Give 500 ml intravenous plasma expander over 4 hours
○	Urgent renal ultrasound

This question is dealing with postoperative acute renal failure. This what you might find on the morning ward round and wonder why the problem was not picked up during the night.

Note that even when the glomerular filtration rate is zero, the serum creatinine tends not to rise faster than 200 micro mol/l per day - so the patient's creatinine of 120 micro mol/l may be the beginning of established renal failure.

Immediate management consists of restoring the circulation as quickly as possible; debate still continues whether it is better to use colloid or crystalloid.

In this case it would seem to be more appropriate to use 1 L of normal saline as the time scale for plasma expander is too long.

If urine output and renal function recover as soon as intravascular volume is restored, the diagnosis of pre-renal uraemia is made; if they do not then the diagnosis is acute tubular necrosis (ATN).

In a seemingly previously cardiovascularly-well 30-year-old with hypotension, giving 1 L over a short time will not precipitate any problems.

There is little evidence to suggest that loop diuretics and dopamine are effective in the treatment of ATN.

The next problem is to find out why the patient was hypotensive after surgery.....

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 22 mins 2 secs

Question: 55 of 100

A 16-year-old male is brought to emergency admissions with alcohol intoxication. An initial electrocardiogram (ECG) reveals atrial fibrillation (AF) but a repeat ECG after 12 hours when he has sobered up, shows sinus rhythm. An echocardiogram is normal.

What is the most appropriate management for this patient?

(Please select 1 option)

- Aspirin for 3 months
- Bisoprolol for 3 months
- Lifestyle advice
- Sotalol for one month
- Warfarin for one month

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 16-year-old male is brought to emergency admissions with alcohol intoxication. An initial electrocardiogram (ECG) reveals atrial fibrillation (AF) but a repeat ECG after 12 hours when he has sobered up, shows sinus rhythm. An echocardiogram is normal.

What is the most appropriate management for this patient?

(Please select 1 option)

○	Aspirin for 3 months
○	Bisoprolol for 3 months
◉	Lifestyle advice ✓ Correct
○	Sotalol for one month
○	Warfarin for one month

Excessive alcohol is a recognised cause for atrial fibrillation and is the likely cause here as the rhythm has reverted to sinus after 12 hours. There is also no evidence of structural heart disease as the echocardiogram was normal.

Therefore this patient needs advice regarding moderation of alcohol consumption and needs to be warned of the toxic effects that alcohol can have on the heart and other organs.

There is no indication for short term aspirin.

Atenolol provides rate control, which is not an issue.

Sotalol/amiodarone and flecainide can be used in paroxysmal AF.

Short term warfarin is used for 4-6 weeks prior to elective cardioversion to protect against embolic complications.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 27 mins 9 secs

Question: 57 of 100

A 72-year-old man with type 2 diabetes mellitus presented following the sudden onset of palpitations.

An ECG revealed rapid atrial fibrillation. He was commenced on amiodarone but the atrial fibrillation persisted.

Which of the following has been shown to be of greatest benefit in reducing his future risk of vascular events?

(Please select 1 option)

- Anticoagulation
- Aspirin
- Continuation of amiodarone
- DC cardioversion
- Digoxin

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 30 mins 2 secs

Question: 58 of 100

An 18-year-old female presents with an acute exacerbation of asthma associated with a chest infection. She is unable to complete a sentence and her peak flow rate was 35% of her normal level.

She is treated with high flow oxygen, nebulised bronchodilators and oral steroids but this is associated with little change in her condition.

Which of the following treatments, given intravenously, would be the most appropriate for this patient?

(Please select 1 option)

- Aminophylline
- Augmentin
- Hydrocortisone
- Magnesium
- Salbutamol

She is treated with high flow oxygen, nebulised bronchodilators and oral steroids but this is associated with little change in her condition.

Which of the following treatments, given intravenously, would be the most appropriate for this patient?

(Please select 1 option)

○	Aminophylline
○	Augmentin
○	Hydrocortisone
◉	Magnesium ✓ Correct
○	Salbutamol

This patient has acute severe asthma (PEFR 33-50% predicted/best, unable to complete sentences in one breath, respiratory rate >25 breaths/min, pulse rate >110 beats/minute).

She has not responded to initial treatment and the treatment of choice now is intravenous magnesium 1.2-2 g over 20 minutes.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 31 mins 35 secs

Question: 59 of 100

A 40-year-old farmer presented to the Emergency Department with a 24 hour history of fever and increasing confusion.

On examination he was febrile 39.5°C. A generalised erythematous rash, covering most of his body, was observed. He also had a paronychial infection of his right index finger, with lymphangitis extending caudally, and with axillary lymphadenopathy.

His heart rate was measured at 120 beats per minute with a blood pressure of 80/60 mmHg.

What is the most likely diagnosis?

(Please select 1 option)

- Hantavirus infection
- Leptospirosis
- Orf
- Staphylococcal toxic shock syndrome
- Stevens-Johnson syndrome

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

http://my.onexamination.com/Assessment/Que
Questions Set : REF6296

◉	Orf ✕ Incorrect answer selected
○	Staphylococcal toxic shock syndrome ← This is the correct answer
○	Stevens-Johnson syndrome

The history is typical of staphylococcal toxic shock syndrome (TSS):

- shock
- fever
- confusion
- rash.

The primary source of infection in this case is the paronychia of his right index finger.

Hantavirus infections (viral zoonoses transmitted via rodents) typically have two distinct presentations:

1. either as a haemorrhagic fever with renal failure
2. or as an acute pulmonary syndrome.

The former manifestation is commonest in the Far East and eastern Europe, while the latter is the predominant form in the southwestern United States and South America.

Leptospirosis does not typically cause a rash and is often associated with jaundice; leptospirosis would not explain the lesion on his finger.

Orf, a zoonotic infection caused by a pox virus, presents with painless ulcerated lesions on the hands of farmers, but does not fully explain this clinical picture.

Stevens-Johnson syndrome typically starts with an erythema multiforme-type rash that spreads widely and involves the buccal mucosa and conjunctivae, often caused by antibiotic therapy; but does not fit the clinical picture presented here.

A 24 year old law student attends with visual loss affecting the right eye. She reports a constant headache for the last three months, and absence of menses for six months.

On examination her visual acuity in the right eye is 6/24, with slight constriction of the temporal field in that eye but she has no other neurological deficit. She is afebrile and haemodynamically stable.

What is the diagnosis?

(Please select 1 option)

○	Glaucoma
○	Migraine
○	Multiple sclerosis
◉	Pituitary tumour ✓ Correct
○	Pregnancy

This patient has a pituitary lesion; the history of headache and amenorrhoea suggests a prolactinoma or non- functioning tumour. This has been complicated by involvement of the visual pathway which has precipitated her visual loss.

She needs urgent assessment of her pituitary function and imaging of the pituitary gland by MRI scanning. One of the most important investigations to perform would be a serum prolactin.

The amenorrhoea would argue against this being retrobulbar neuritis associated with multiple sclerosis (MS), and similarly the peripheral visual field constriction would be unusual as a central scotoma and fluctuating visual loss would be more typical.

Question: 6 of 100

A 52-year-old woman presents with left loin pain. Past history included hypertension and progressive cognitive decline.

On examination she was pyrexial, had livedo reticularis and a blood pressure of 180/100 mmHg. Examination of the abdomen revealed no masses but there was tenderness in the left flank.

Investigations revealed:

Haemoglobin	12.9 g/dl	(11.5-16.5)
White cell count	8.7 x 10^9/l	(4-11)
Platelet count	83 x 10^9/l	(150-400)
Serum creatinine	106 mol/l	(60-110)

Urine dipstick analysis:
Blood +++
Protein +

Which one of the following tests is most likely to be positive?

(Please select 1 option)

- Anti-cardiolipin antibody
- Anti-glomerular basement membrane antibody
- Anti-mitochondrial antibody
- Anti-neutrophil cytoplasmic antibody
- Anti-streptolysin O antibody

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 34 mins 46 secs

Question: 60 of 100

A 29-year-old female presents with acute right-sided weakness.

She has one child aged four years and had two spontaneous abortions in the past. After the birth of her child she developed a DVT and required three months' anticoagulation with warfarin.

Examination revealed a right hemiparesis. A CT head scan showed a left middle cerebral artery territory infarct.

What is the most likely finding on echocardiography?

(Please select 1 option)

- Atrial septal defect
- Bicuspid aortic valve
- Left atrial myxoma
- Normal appearances
- Ventricular septal defect

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Question: 60 of 100

A 29-year-old female presents with acute right-sided weakness.

She has one child aged four years and had two spontaneous abortions in the past. After the birth of her child she developed a DVT and required three months' anticoagulation with warfarin.

Examination revealed a right hemiparesis. A CT head scan showed a left middle cerebral artery territory infarct.

What is the most likely finding on echocardiography?

(Please select 1 option)

○	Atrial septal defect
○	Bicuspid aortic valve
○	Left atrial myxoma
◉	Normal appearances ✓ Correct
○	Ventricular septal defect

This patient has a prothrombotic tendency suggestive of the lupus anticoagulant with recurrent abortions, previous deep vein thrombosis (DVT) and now she has developed a left hemiparesis.

This has occurred off warfarin and it is highly unlikely to be due to any right to left transference of clot.

It is more likely to be due to spontaneous infarct related to the thrombophilia and her heart is likely to be normal.

Next question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Question: 61 of 100

A 42-year-old female is admitted following an overdose of diazepam and alcohol.

On examination she was unconscious with a core temperature of 34.5°C and a blood pressure of 110/80 mmHg.

Investigations reveal:

Creatinine	242 µmol/l	(60-100)
AST	500 U/l	(0-40)
Gamma GT	35 U/l	(<50)
Urine microscopy	No cells or organisms	
Urine dipstick analysis blood	+++	
Ultrasound abdomen	Normal	

Which one of the following is the most likely cause of these findings?

(Please select 1 option)

- Associated paracetamol poisoning
- Chronic renal failure
- Dehydration
- Hypothermia
- Rhabdomyolysis

Creatinine	242 µmol/l	(60-100)
AST	500 U/l	(0-40)
Gamma GT	35 U/l	(<50)
Urine microscopy	No cells or organisms	
Urine dipstick analysis blood	+++	
Ultrasound abdomen	Normal	

Which one of the following is the most likely cause of these findings?

(Please select 1 option)

- ○ Associated paracetamol poisoning
- ○ Chronic renal failure
- ○ Dehydration
- ○ Hypothermia
- ◉ Rhabdomyolysis ✓ Correct

This patient has taken an overdose of diazepam and has collapsed for an indeterminate period. She is now seen with renal impairment.

The features together with the elevated amino transferase (AST) (from muscle) suggest a diagnosis of rhabdomyolysis.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 37 mins 40 secs

Question: 62 of 100

A 40-year-old man suffers an intracerebral infarction.

Which of the following features in this patient would not be considered as a risk factor for his stroke?

(Please select 1 option)

- Blood pressure 156/72 mmHg
- Marijuana use
- Mitral valve prolapse
- Plasma cholesterol of 6.5 mmol/l
- Smoker of 5 cigarettes per day

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 38 mins 20 secs

Question: 62 of 100

A 40-year-old man suffers an intracerebral infarction.

Which of the following features in this patient would not be considered as a risk factor for his stroke?

(Please select 1 option)

○	Blood pressure 156/72 mmHg
◉	Marijuana use ✓ Correct
○	Mitral valve prolapse
○	Plasma cholesterol of 6.5 mmol/l
○	Smoker of 5 cigarettes per day

Like ischaemic heart disease/myocardial infarction (IHD/MI), epidemiological studies show an increased risk of stroke associated with hypercholesterolaemia. Other risk factors for stroke include isolated systolic hypertension in particular.

A previous history of deep vein thrombosis (DVT) may suggest a coagulation disorder.

Cocaine is associated with an increased risk of intracerebral infarction; marijuana is associated with increased susceptibility to schizophrenic episodes, particularly in the younger age group.

A 35-year-old male with a long history of ulcerative colitis is treated for an acute exacerbation which settles following an alteration of his medication.

Six weeks after discharge he is re-admitted with sepsis and his results show:

Haemoglobin	10.5 g/dl	(13.0-18.0)
White cell count	2.0 x 10^9/l	(4-11)
Platelets	90 x 10^9/l	(150-400)

Which one of the following drugs is most likely to be the cause of his pancytopaenia?

(Please select 1 option)

- (●) Azathioprine ✓ Correct
- ( ) Mesalazine
- ( ) Metronidazole
- ( ) Pamidronate
- ( ) Prednisolone

The answer could be either azathioprine or mesalazine as both cause a pancytopaenia although azathioprine is the more common cause.

Hence it is a toss up but one would have to go for azathioprine.

Work Smart Session - MRCP Part 1

Question: 64 of 100

A 65-year-old male presents with acute severe headache, ataxia and vomiting. Six hours later he became drowsy.

On examination he had left horizontal nystagmus, a partial left sixth cranial nerve palsy and extensor plantar responses. His blood pressure was 188/110 mmHg.

What is the most likely cause for this deterioration?

(Please select 1 option)

○	Brain stem herniation ← This is the correct answer
◉	Cerebral oedema ✕ Incorrect answer selected
○	Dehydration
○	Malignant hypertension
○	Non-convulsive status epilepticus

The most likely explanation of the sudden deterioration will be brain stem herniation.

The acute onset of symptoms with headache and vomiting indicating an acute intracranial haemorrhage.

Mass effect created the brain stem herniation.

Intravenous mannitol, intubation/ventilation, urgent computerised tomography (CT) brain scan and neurosurgical referral are indicated.

Work Smart Session - MRCP Part 1

Time taken: 3 hrs 41 mins 14 secs

Question: 65 of 100

A 78-year-old female with diabetes presented with a two day history of melaena and dizziness. She had taken an unknown analgesic four days previously.

On examination she was pale with a pulse of 90 beats per minute, a blood pressure of 100/65 mmHg and a lower midline scar from an operation for intermittent claudication three months previously.

Investigations revealed:

Haemoglobin	8 g/dl	(13.0-18.0)
Faecal occult blood	Strongly positive	
Upper gastrointestinal tract endoscopy	Normal	

What is the most likely cause of her upper gastrointestinal (GI) haemorrhage?

(Please select 1 option)

- ○ Aorto-enteric fistula
- ○ Gastric erosions
- ○ Gastric ulcer (GU)
- ○ Mallory-Weiss syndrome
- ○ Oesophageal varices

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd. All rights reserved. Terms and conditions. Privacy policy.

Investigations revealed:

Haemoglobin	8 g/dl	(13.0-18.0)
Faecal occult blood	Strongly positive	
Upper gastrointestinal tract endoscopy	Normal	

What is the most likely cause of her upper gastrointestinal (GI) haemorrhage?

(Please select 1 option)

- Aorto-enteric fistula ← This is the correct answer
- (●) Gastric erosions ✗ Incorrect answer selected
- Gastric ulcer (GU)
- Mallory-Weiss syndrome
- Oesophageal varices

The upper GI endoscopy is normal, therefore GU, gastric erosions, varices and Mallory-Weiss syndrome are unlikely.

The strongly positive faecal occult blood (FOB) suggests significant GI haemorrhage.

Aorto-enteric fistulae (AEF) are now known to occur following endovascular repair of abdominal aortic aneurysms (AAA), and secondary to aortic grafting of any kind, presumably because of mechanical forces of dislodged or migrating devices.

This patient may well have had an aorto-bifemoral graft, as treatment for peripheral vascular disease.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 6 mins 41 secs

Question: 66 of 100

An 18-year-old woman presents three days after allegedly taking 50 paracetamol tablets (25 g).

Which of the following tests measured at this time point would be most helpful in determining the outcome?

(Please select 1 option)

- ALT concentration
- Bilirubin concentration
- Creatinine concentration
- Paracetamol concentration
- Prothrombin time

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

○	Bilirubin concentration
○	Creatinine concentration
○	Paracetamol concentration
◉	Prothrombin time ✓ Correct

The patient has ingested a seriously toxic dose of paracetamol.

The best determinant of this risk at 72 hours would be a prolonged prothrombin time.

Paracetamol concentrations would be rather meaningless at this point in time, and irrespective, she should be treated with N-acetylcysteine.

There are four phases of paracetamol overdose:

Phase 1 (0-24 hours)

- Asymptomatic
- Anorexia
- Nausea or vomiting
- Malaise
- Subclinical rise in serum aspartate transaminase (AST) - 12 hours post ingestion.

Phase 2 (18-72 hours)

- Right upper quadrant abdominal pain, anorexia, nausea, vomiting
- Continued rise in serum transaminases levels (note this is the time slot for our patient with the alanine transaminase [ALT] rises).

Phase 3 (72-96 hours)

- Anorexia
- Nausea or vomiting
- Malaise
- Subclinical rise in serum aspartate transaminase (AST) - 12 hours post ingestion.

Phase 2 (18-72 hours)

- Right upper quadrant abdominal pain, anorexia, nausea, vomiting
- Continued rise in serum transaminases levels (note this is the time slot for our patient with the alanine transaminase [ALT] rises).

Phase 3 (72-96 hours)

- Centrilobular hepatic necrosis with continued abdominal pain
- Jaundice
- Coagulopathy
- Hepatic encephalopathy
- Nausea and vomiting
- Renal failure
- Fatality rising international normalised ratio/prothrombin time (INR/PT) from three days.

Phase 4 (Four days to three weeks)

- Complete resolution of symptoms
- Complete resolution of organ failure.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 7 mins 39 secs

Question: 67 of 100

These are the blood gas results obtained from a 20-year-old female admitted to hospital.

Hydrogen ion concentration	35 nmol/l	(35-45)
pH	7.45	(7.36-7.44)
pCO_2	6.8 kPa	(4.7-6.0)
Bicarbonate	32 mmol/l	(20-28)

Which of the following is the most likely cause of this patient's acid-base derangement?

(Please select 1 option)

- Amitriptyline overdose
- Cushing's syndrome
- Hepatic failure
- Pregnancy
- Salicylate poisoning

Submit answer | Skip question | Tag Question | Remove question

Hydrogen ion concentration	35 nmol/l	(35-45)
pH	7.45	(7.36-7.44)
pCO_2	6.8 kPa	(4.7-6.0)
Bicarbonate	32 mmol/l	(20-28)

Which of the following is the most likely cause of this patient's acid-base derangement?

(Please select 1 option)

- ○ Amitriptyline overdose
- ○ Cushing's syndrome
- ○ Hepatic failure
- ◉ Pregnancy ✓ Correct
- ○ Salicylate poisoning

This patient has a mild metabolic alkalosis with what appears to be respiratory compensation as reflected by the elevated pCO_2.

Amitriptyline overdose is associated with acidosis as is salicylate poisoning.

Hepatic failure usually presents with acidosis.

This type of picture is associated with prolonged vomiting (as in pregnancy), diarrhoea, diuretic therapy and in Cushing's syndrome, or in those receiving high dose corticosteroids. With no other information provided for this case, common things being common, one should select pregnancy as the best answer for a 20-year-old female.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 9 mins 56 secs

Question: 68 of 100

A 70-year-old male is admitted with haematemesis. He is currently being treated with warfarin for atrial fibrillation and his INR returns as 10 (<1.4).

Which of the following is the most appropriate immediate treatment of his INR?

(Please select 1 option)

- Cryoprecipitate
- Fresh frozen plasma
- Intravenous vitamin K
- Oral vitamin K
- Recombinant Factor VIII concentrate

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 11 mins 55 secs

Question: 68 of 100

A 70-year-old male is admitted with haematemesis. He is currently being treated with warfarin for atrial fibrillation and his INR returns as 10 (<1.4).

Which of the following is the most appropriate immediate treatment of his INR?

(Please select 1 option)

○	Cryoprecipitate
◉	Fresh frozen plasma ✓ Correct
○	Intravenous vitamin K
○	Oral vitamin K
○	Recombinant Factor VIII concentrate

This patient has had a bleed related to a grossly elevated international normalised ratio (INR). Consequently the INR needs correction as rapidly as is possible.

Vitamin K will correct the INR over a few days, whereas fresh frozen plasma will correct the bleeding time rapidly.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 11 mins 55 secs

Question: 69 of 100

You have been called to the ward by the senior nurse, to review a repeat calcium result. The repeat result is 3.9 mmol/l (2.2-2.6), the previous result four hours earlier was 3.2.

The patient has a disseminated malignancy with an unknown primary.

Which of the following statements is most correct when considering the hypercalcaemia of malignancy?

(Please select 1 option)

- A prolonged QT interval is associated with hypercalcaemia
- Bisphosphonates inhibit osteoblast function thereby lowering calcium
- Calcitonin is of greater benefit than bisphosphonates in the treatment of hypercalcaemia of malignancy
- NSAIDs are indicated for bone pain in this patient
- On neurological examination, hyporeflexia may be exhibited

Submit answer | Skip question | Tag Question | Remove question

The patient has a disseminated malignancy with an unknown primary.

Which of the following statements is most correct when considering the hypercalcaemia of malignancy?

(Please select 1 option)

◉	A prolonged QT interval is associated with hypercalcaemia ✕ Incorrect answer selected
○	Bisphosphonates inhibit osteoblast function thereby lowering calcium
○	Calcitonin is of greater benefit than bisphosphonates in the treatment of hypercalcaemia of malignancy
○	NSAIDs are indicated for bone pain in this patient
○	On neurological examination, hyporeflexia may be exhibited ← This is the correct answer

This is an oncological emergency.

Hyporeflexia is a common clinical sign in patients with hypercalcaemia.

Non-steroidal anti-inflammatory drugs (NSAIDs) should not be prescribed in patients with hypercalcaemia as they reduce renal blood flow thus inhibiting urinary calcium excretion.

Bisphosphonates inhibit bone resorption by osteoclasts, and are the first line pharmacological treatment of hypercalcaemia of malignancy; calcitonin use is limited by its association with anaphylaxis.

Electrocardiogram changes in hypercalcaemia include bradycardia, prolonged PR interval, short QT interval, widened T waves and arrhythmias.

White cell count	8.7 x 10^9/l	(4-11)
Platelet count	83 x 10^9/l	(150-400)
Serum creatinine	106 mol/l	(60-110)

Urine dipstick analysis:
Blood +++
Protein +

Which one of the following tests is most likely to be positive?

(Please select 1 option)

- (●) Anti-cardiolipin antibody ✓ Correct
- ( ) Anti-glomerular basement membrane antibody
- ( ) Anti-mitochondrial antibody
- ( ) Anti-neutrophil cytoplasmic antibody
- ( ) Anti-streptolysin O antibody

This patient has features to suggest systemic lupus erythematosus (SLE) with antiphospholipid syndrome in this presentation, possibly due to renal vein thrombosis (flank pain with blood and protein in urine).

The diagnosis would be supported by the thrombocytopenia, history of hypertension and the livedo reticularis.

Wegener's with positive anti-neutrophil cytoplasmic antibody (ANCA) would be a less likely diagnosis.

Work Smart Session - MRCP Part 1

Time taken: 33 mins 18 secs

Question: 7 of 100

A 35-year-old woman with known seafood allergy presented after developing an itchy rash at a restaurant. She had widespread urticaria which spared her neck and face.

On examination, her blood pressure is 130/70 mmHg, pulse 95 bpm, respiratory rate 24/min and O_2 saturation 99% on air.

Intravenous hydrocortisone and intramuscular antihistamine have been given.

What is the next most appropriate step in the management of this patient?

(Please select 1 option)

- Inhaled adrenaline
- Intramuscular adrenaline
- Intravenous adrenaline
- Observe
- Subcutaneous adrenaline

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 14 mins 39 secs

Question: 70 of 100

A 70-year-old female who has a history of chronic anxiety presents with a three day history of severe left temporal headache radiating from the eye to the scalp. She had also experienced discomfort during eating.

Which one of the following drugs should be given to this patient while awaiting the results of diagnostic tests?

(Please select 1 option)

○	Acyclovir
○	Carbamazepine
○	Diclofenac
◉	Prednisolone ✓ Correct
○	Sumatriptan

The history suggests temporal arteritis irrespective of the history of anxiety and in view of the sight-threatening nature of the disease, the patient should be commenced on steroids.

Although the differential diagnosis is also trigeminal neuralgia, steroids should be used here whilst awaiting diagnostic investigations as temporal arteritis may be sight-threatening if left untreated.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 14 mins 39 secs

Question: 71 of 100

A 52-year-old male is admitted with haematemesis and melaena.

Examination reveals that he is icteric, confused with a flapping tremor, has signs of chronic liver disease, a pulse rate of 110 bpm and blood pressure of 100/70 mmHg. Abdominal examination reveals ascites.

An urgent endoscopy reveals small oesophageal varices, without evidence of bleeding, but an oozing portal hypertensive gastropathy.

Which of the following measures would be the most appropriate treatment for this patient?

(Please select 1 option)

○	Endoscopic banding
○	Endoscopic injection of adrenaline
○	Endoscopic injection of ethanolamine
○	Intravenous vitamin K
○	Oral propranolol

Submit answer | Skip question | Remove Tag | Remove question

A 52-year-old male is admitted with haematemesis and melaena.

Examination reveals that he is icteric, confused with a flapping tremor, has signs of chronic liver disease, a pulse rate of 110 bpm and blood pressure of 100/70 mmHg. Abdominal examination reveals ascites.

An urgent endoscopy reveals small oesophageal varices, without evidence of bleeding, but an oozing portal hypertensive gastropathy.

Which of the following measures would be the most appropriate treatment for this patient?

(Please select 1 option)

○	Endoscopic banding
◉	Endoscopic injection of adrenaline ✓ Correct
○	Endoscopic injection of ethanolamine
○	Intravenous vitamin K
○	Oral propranolol

The endoscopy shows small varices with no evidence of bleeding but diffuse oozing of blood. Hence endoscopic measures like banding for small varices will not be useful.

There is probably no evidence that vitamin K is helpful, as the coagulation is already likely to be deranged.

Oral propranolol is useful as a later prophylaxis of variceal bleed.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 15 mins 39 secs

Question: 72 of 100

A 55-year-old male presented six hours after taking an overdose of lithium tablets which had been prescribed for a bipolar affective disorder.

On examination he was tremulous, had suffered a convulsion and had a Glasgow coma scale of 12/15. His serum lithium concentration was 5.0 mmol/L (0.5-1.0)

What is the most appropriate management of this patient?

(Please select 1 option)

○	Activated charcoal
○	Forced alkaline diuresis
○	Furosemide 100 mg intravenously twice daily
○	Haemodialysis
○	Measure lithium concentration in 2 hours

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 55-year-old male presented six hours after taking an overdose of lithium tablets which had been prescribed for a bipolar affective disorder.

On examination he was tremulous, had suffered a convulsion and had a Glasgow coma scale of 12/15. His serum lithium concentration was 5.0 mmol/L (0.5-1.0)

What is the most appropriate management of this patient?

(Please select 1 option)

○	Activated charcoal
○	Forced alkaline diuresis
○	Furosemide 100 mg intravenously twice daily
◉	Haemodialysis ✓ Correct
○	Measure lithium concentration in 2 hours

The patient has a severe lithium overdose as reflected by markedly elevated lithium concentrations and features of impaired consciousness, tremor and seizures.

This needs urgent management.

Activated charcoal does not bind lithium effectively and is therefore ineffective except where co-ingestion of other poisons is suspected.

Haemodialysis is the mainstay of treatment for acute lithium toxicity.

Work Smart Session - MRCP Part 1

Question: 73 of 100

An 18-year-old woman sustains severe head injuries in a road traffic accident.

The following day her investigations show:

Sodium	160 mmol/l	(137-144)
Potassium	3.7 mmol/l	(3.5-4.9)
Chloride	120 mmol/l	(95-107)
Urea	3.0 mmol/l	(2.5-7.5)
Creatinine	90 µmol/l	(60- 110)

Which one of the following statements is correct?

(Please select 1 option)

- Rapid rehydration with 5% dextrose is indicated
- She has the syndrome of inappropriate antidiuretic hormone secretion (SIADH)
- She should be treated with sodium restriction
- She will have a hypercholraemic acidosis
- Urine osmolality will be low

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 19 mins 23 secs

Question: 74 of 100

A 60-year-old woman presents with raised, erythematous lesions on the limbs and blistering in the mouth and eyes. She had been taking a number of drugs prescribed by her GP.

Which may be responsible for her presentation?

(Please select 1 option)

- Nifedipine
- Paracetamol
- Paroxetine
- Prednisolone
- Sulphasalazine

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

○	Prednisolone
◉	Sulphasalazine ✓ Correct

This is a typical case of Stevens-Johnson syndrome.

Stevens-Johnson syndrome (SJS) is an immune-complex-mediated hypersensitivity complex that is a severe expression of erythema multiforme. It is now known also as erythema multiforme major.

SJS typically involves the skin and the mucous membranes. While minor presentations may occur, significant involvement of:

- oral
- nasal
- eye
- vaginal
- urethral
- gastrointestinal (GI)
- lower respiratory tract mucous membranes

may develop in the course of the illness.

GI and respiratory involvement may progress to necrosis.

SJS is a serious systemic disorder with the potential for severe morbidity and even death.

The drugs most closely associated with causing Stevens-Johnson syndrome are:

- antibacterials
- sulfonamides
- anticonvulsants (oxicam)
- non-steroidal anti-inflammatory agents (piroxicam and tenoxicam)
- chlormezanone
- allopurinol.

Work Smart Session - MRCP Part 1

Question: 75 of 100

A 58-year-old man presents with a month history of breathlessness. He was a non-smoker.

On examination, his temperature was 36.7°C, with a respiratory rate of 20 breaths per minute and normal breath sounds to auscultation and a pulse of 92 bpm.

Arterial blood gases on air showed:

pH	7.51 (7.36 - 7.44)
pO_2	8.4 kPa (11.3 - 12.6)
pCO_2	4.0 kPa (4.7 - 6.0)

What is the most likely diagnosis?

(Please select 1 option)

- Atypical pneumonia
- Fibrosing alveolitis
- Hysterical hyperventilation
- Inhaled foreign body
- Pulmonary thromboembolism

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Arterial blood gases on air showed:

pH	7.51 (7.36 - 7.44)
pO_2	8.4 kPa (11.3 - 12.6)
pCO_2	4.0 kPa (4.7 - 6.0)

What is the most likely diagnosis?

(Please select 1 option)

- Atypical pneumonia
- Fibrosing alveolitis ✕ Incorrect answer selected
- Hysterical hyperventilation
- Inhaled foreign body
- Pulmonary thromboembolism ← This is the correct answer

This patient has a respiratory alkalosis with type 1 respiratory failure as evidenced by low pO_2 and low pCO_2.

Chronic venous thromboembolism would be the most likely explanation for this man's presentation.

Hyperventilation would be excluded by the type 1 respiratory failure, an inhaled foreign body would not produce such a picture and an atypical pneumonia would be associated with pyrexia and some clinical signs.

The differential diagnosis here is pulmonary fibrosis but basal crackles may be expected and the history is somewhat short.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 34 mins 37 secs

Question: 76 of 100

A 50-year-old male presented with acute respiratory failure during an episode of acute pancreatitis and was thought to have developed adult respiratory distress syndrome (ARDS).

Which of the following would support a diagnosis of ARDS?

(Please select 1 option)

- ○ High protein pulmonary oedema
- ○ High pulmonary capillary wedge pressure
- ○ Hypercapnia
- ○ Increased lung compliance
- ○ Normal chest x ray

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

developed adult respiratory distress syndrome (ARDS).

Which of the following would support a diagnosis of ARDS?

(Please select 1 option)

◉	High protein pulmonary oedema ✓ Correct
○	High pulmonary capillary wedge pressure
○	Hypercapnia
○	Increased lung compliance
○	Normal chest x ray

ARDS is characterised by:

- hypoxaemia
- reduced lung compliance
- pulmonary hypertension
- pulmonary infiltrates on the chest x ray.

There is damage to the capillary and endothelial cell linings resulting in oedema and leakage of proteins and cells into the interstitial and alveolar spaces at normal pulmonary capillary hydrostatic pressures.

Wedge pressure, unlike the high pressures seen with left ventricular failure (LVF) and pulmonary oedema, is often normal.

Hypercapnia, often a late feature of ARDS, does not distinguish from any other cause of type 2 respiratory failure.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 40 mins 37 secs

Question: 77 of 100

A 55-year-old nurse developed bronchospasm and urticaria twenty minutes into surgery under general anaesthesia.

The mast cell tryptase concentration confirmed an acute allergic reaction.

Later, it transpired that she had developed allergic reactions at her dentist and had developed frequent episodes of wheezing when assisting at sterile procedures.

What is the most likely diagnosis?

(Please select 1 option)

- Allergy to anaesthetic induction agents
- Allergy to local anaesthetic agents
- Latex allergy
- Pressure urticaria
- Systemic mastocytosis

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

What is the most likely diagnosis?

(Please select 1 option)

○	Allergy to anaesthetic induction agents
○	Allergy to local anaesthetic agents
◉	Latex allergy ✓ Correct
○	Pressure urticaria
○	Systemic mastocytosis

This patient developed anaphylaxis during a surgical procedure and it appears that she had problems with allergies during dental treatment and whilst assisting during sterile procedures.

This would suggest that she is allergic to latex rather than induction agents or local anaesthesia as latex would be present in all three of the above procedures.

Systemic mastocytosis is a disease which usually affects the elderly and is associated with:

- urticaria pigmentosa
- diarrhoea
- hypotension
- sclerotic bone changes and
- mast cell infiltration of organs such as spleen, liver and kidneys.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 42 mins 20 secs

Question: 78 of 100

A 42-year-old woman presents with an acute attack of asthma. She is able to speak in short sentences.

Her respiratory rate is 28 breaths per minute and the peak expiratory flow rate 120 L/min (predicted 480 L/min.

What is the most appropriate treatment for this patient?

(Please select 1 option)

○	Intravenous aminophylline
○	Intravenous salbutamol
○	Nebulised salbutamol
○	Oral salbutamol
○	Oral theophylline

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 42-year-old woman presents with an acute attack of asthma. She is able to speak in short sentences.

Her respiratory rate is 28 breaths per minute and the peak expiratory flow rate 120 L/min (predicted 480 L/min.

What is the most appropriate treatment for this patient?

(Please select 1 option)

○	Intravenous aminophylline
○	Intravenous salbutamol
◉	Nebulised salbutamol ✓ Correct
○	Oral salbutamol
○	Oral theophylline

This patient has features of acute severe asthma, and should be given oxygen, steroids and nebulised salbutamol as immediate treatment.

Although the PFR is less than 33% of predicted normal (feature of life-threatening attack), we do not know what her previous best is. It could be low, for example, 240 L/min.

If it had been a life-threatening attack, nebulised ipratropium and intravenous aminophylline, salbutamol or terbutaline should be given. The guidelines do not specify a preference.

This is another clue that the answer should be nebulised salbutamol.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 43 mins 42 secs

Question: 79 of 100

A 72-year-old man presents with an episode of collapse.

He has had two similar episodes recently, each lasting about one minute. Four years ago he suffered an anterior myocardial infarction.

On examination he was orientated and symptom-free with a regular pulse rate of 80 bpm, BP 140/80 mmHg and the apex beat was displaced to the left. There was an apical systolic murmur.

There were no signs of trauma. ECG showed sinus rhythm, Q waves and ST segment elevation anteriorly without reciprocal depression.

What is the diagnosis?

(Please select 1 option)

- Acute anterior myocardial infarction
- Cerebrovascular accident
- Epileptic seizure
- Pulmonary embolism
- Ventricular tachycardia

Submit answer | Skip question | Tag Question | Remove question

displaced to the left. There was an apical systolic murmur.

There were no signs of trauma. ECG showed sinus rhythm, Q waves and ST segment elevation anteriorly without reciprocal depression.

What is the diagnosis?

(Please select 1 option)

○	Acute anterior myocardial infarction
◉	Cerebrovascular accident ✗ Incorrect answer selected
○	Epileptic seizure
○	Pulmonary embolism
○	Ventricular tachycardia ← This is the correct answer

The electrocardiogram is suggestive of a left ventricular (LV) aneurysm, which has a tendency for both a malignant arrhythmogenic focus and also for left ventricular thrombus.

The brief episode of loss of consciousness with no residual neurology makes the diagnosis for cerebral embolism unlikely.

The story is more suggestive of a ventricular tachycardia (VT) and would suggest further investigations. Prolonged heart rhythm monitoring and an echo are recommended.

If VT is proven then he should be on amiodarone and the indication for an automated implantable cardioverter/defibrillator strongly considered if the overall LV function is reduced.

Next question | Remove Tag | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

On examination, her blood pressure is 130/70 mmHg, pulse 95 bpm, respiratory rate 24/min and O_2 saturation 99% on air.

Intravenous hydrocortisone and intramuscular antihistamine have been given.

What is the next most appropriate step in the management of this patient?

(Please select 1 option)

○	Inhaled adrenaline
○	Intramuscular adrenaline
○	Intravenous adrenaline
◉	Observe ✓ Correct
○	Subcutaneous adrenaline

Where there is a history of a typical allergic reaction as here current United Kingdom resuscitation guidelines suggest adrenaline if there is:

- stridor
- wheeze
- respiratory distress or
- clinical evidence of shock.

A literature review in the BMJ includes a copy of the algorithm and a discussion of the evidence for adrenaline. BMJ 2003;327:1332-1335

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 47 mins 41 secs

Question: 80 of 100

A 59-year-old man who was active all his life develops sudden severe anterior chest pain that radiates to his back. Within minutes, he is unconscious.

He has a history of hypertension, but a recent treadmill test had revealed no evidence for cardiac disease.

Which of the following is the most likely diagnosis?

(Please select 1 option)

○	Acute myocardial infarction (MI)
○	Group A streptococcal infection
○	Pulmonary embolus
○	Right middle cerebral artery embolus
◉	Tear in the aortic intima ✓ Correct

The history is typical of aortic dissection.

All the others could cause sudden collapse but not with acute chest pain radiating to the back in the presence of a recent normal exercise test.

Acute MI is possible but not the most likely.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 52 mins 38 secs

Question: 82 of 100

A 30-year-old man presents with a history of transient loss of consciousness and palpitations. His ECG shows ventricular tachycardia (VT).

Which of the following treatments should be avoided?

(Please select 1 option)

- Adenosine
- Amiodarone
- DC cardioversion
- Flecainide
- Verapamil

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Which of the following treatments should be avoided?

(Please select 1 option)

○	Adenosine
○	Amiodarone
○	DC cardioversion
○	Flecainide
◉	Verapamil ✓ Correct

If there were 'killer' questions (questions that if a candidate got wrong they would certainly fail the exam) in the MRCP examination then this would be one of them.

Verapamil should be avoided in cases of VT because it can cause a catastrophic fall in blood pressure.

Adenosine is useful diagnostically when the diagnosis of regular wide complex tachycardia is in doubt.

Amiodarone is a useful antiarrhythmic agent though its use acutely is limited by its irritant nature on veins.

DC cardioversion is probably the treatment of choice in this case.

Flecainide is a good antiarrhythmic and would be indicated in patients without left ventricular (LV) failure (it is associated with an increased risk of death in such cases).

Flecainide is widely used for atrial fibrillation.

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 53 mins 58 secs

Question: 83 of 100

A 30-year-old man presents to the Emergency Department with a history of drug overdose.

He is known to be repeatedly admitted with similar episodes of self-harm. On this occasion he is drowsy and has prominent hypersalivation.

Which of the following agents, found on his person, is the likely cause?

(Please select 1 option)

- Chlormethiazole
- Cocaine
- Dosulepin
- L-dopa
- Solvent cannister

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Shop

(Please select 1 option)

○	Chlormethiazole ← This is the correct answer
○	Cocaine
◉	Dosulepin ✕ Incorrect answer selected
○	L-dopa
○	Solvent cannister

Hypersalivation is seen with:

- parasympathomimetic agents
- insecticides
- arsenic
- strychnine
- chlormethiazole
- clozapine

and others.

Solvent abuse may cause an acneiform rash around the buccal cavity.

Cocaine abuse leads to hypertension and nasal septum perforation.

The other agents are anticholinergic and would cause dry mouth in overdose.

In considering the management of convulsions select the correct statement from the list below.

(Please select 1 option)

◉	Hypoglycaemia should always be considered. ✓ Correct
○	If the fit lasts longer than five minutes, then PR diazepam should be given.
○	Paraldehyde is best given intramuscularly.
○	Phenobarbitone is a useful therapy in school age children.
○	When associated with fever, antibiotics should always be given to cover the possibility of meningitis.

Status epilepticus is defined as continuous convulsion lasting longer than 30 minutes, or the occurrence of serial convulsions between which there is no return of consciousness. It may be generalised (tonic clonic, absent) or partial (simple, complex, or with secondary generalisation). Generalised tonic clonic seizures predominate. There are 3 major sub-types:

- Prolonged febrile seizures.
- Idiopathic status epilepticus (no underlying central nervous system [CNS] lesion or insult).
- Symptomatic (long-standing neurological disorder or metabolic abnormality).

The most common cause in a child less than 3 years is a prolonged febrile seizure. Sleep deprivation and drug withdrawal can also precipitate it.

The relationship between neurological outcome and duration of status epilepticus is unknown in children and adults. In the animal model, 60 minutes of constant seizure activity is associated with pathological changes, even when metabolic homeostasis is maintained.

Cell death thus results in increased metabolic demands from continually discharging neurones. Vulnerable areas include the hippocampus, the mid to low cerebellum, middle cortical areas, and thalamus.

Approximately 20 minutes of status epilepticus produces regional oxygen sufficiency deficiency promoting cell damage and necrosis. This is, therefore, used as the threshold in children.

Initial management begins with ABC. Hypoglycaemia should be excluded (if present 5ml/kg of 10% dextrose is given by IV infusion), and blood obtained for full blood count, electrolytes including calcium and magnesium, glucose, creatinine, anticonvulsant levels. Blood and urine may be

Paraldehyde is best given intramuscularly.

Phenobarbitone is a useful therapy in school age children.

When associated with fever, antibiotics should always be given to cover the possibility of meningitis.

Status epilepticus is defined as continuous convulsion lasting longer than 30 minutes, or the occurrence of serial convulsions between which there is no return of consciousness. It may be generalised (tonic clonic, absent) or partial (simple, complex, or with secondary generalisation). Generalised tonic clonic seizures predominate. There are 3 major sub-types:

- Prolonged febrile seizures.
- Idiopathic status epilepticus (no underlying central nervous system [CNS] lesion or insult).
- Symptomatic (long-standing neurological disorder or metabolic abnormality).

The most common cause in a child less than 3 years is a prolonged febrile seizure. Sleep deprivation and drug withdrawal can also precipitate it.

The relationship between neurological outcome and duration of status epilepticus is unknown in children and adults. In the animal model, 60 minutes of constant seizure activity is associated with pathological changes, even when metabolic homeostasis is maintained.

Cell death thus results in increased metabolic demands from continually discharging neurones. Vulnerable areas include the hippocampus, the mid to low cerebellum, middle cortical areas, and thalamus.

Approximately 20 minutes of status epilepticus produces regional oxygen sufficiency deficiency promoting cell damage and necrosis. This is, therefore, used as the threshold in children.

Initial management begins with ABC. Hypoglycaemia should be excluded (if present 5ml/kg of 10% dextrose is given by IV infusion), and blood obtained for full blood count, electrolytes including calcium and magnesium, glucose, creatinine, anticonvulsant levels. Blood and urine may be obtained for toxicology. Arterial blood gases should be done, and consideration given to lumbar puncture.

First line anticonvulsant therapy would be Lorazepam/Diazepam given IV if possible. If seizures persist then phenytoin may be given as a loading dose followed by an infusion. Phenobarbitone may be used as first line in infants. Paraldehyde can be given as a dilute solution intravenously, or administered rectally or IM. The latter two routes can produce tissue damage and sloughing, so these should be reserved for exceptional circumstances.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 6 mins 1 secs

Question: 85 of 100

Which of the following concerning the use of intravenous bicarbonate in cardiorespiratory arrest is correct?

(Please select 1 option)

○	Exacerbates intracellular acidosis ← This is the correct answer
◉	Has a positive inotropic effect on ischaemic myocardium ✕ Incorrect answer selected
○	Improves oxygen release to the tissues
○	Increases cerebral blood flow
○	Reduces pre-existent hyperkalaemia

Bicarbonate therapy can increase extracellular pH only if the carbon dioxide (CO_2) produced can be removed by adequate ventilation.

Indeed, if hypercapnia occurs then as CO_2 crosses cell membranes easily, intracellular pH may decrease even further with further deterioration of cellular function.

Bicarbonate has a negative inotropic effect, reducing cerebral blood flow; it shifts the oxygen dissociation curve to the left, inhibiting oxygen release to tissues.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 7 mins 35 secs

Question: 86 of 100

Which of the following statements concerning the treatment of acute myocardial infarction (MI) is correct?

(Please select 1 option)

○	A pansystolic murmur developing within the first 24 hours does not require further investigation
◉	Dipyridamole therapy reduces reinfarction within the first year ✕ Incorrect answer selected
○	Heparin is beneficial if given with streptokinase
○	Prophylactic lidocaine given in the first 48 hours is effective in preventing ventricular fibrillation
○	Treatment with a dihydropyridine calcium antagonist is associated with increased cardiovascular mortality ← This is the correct answer

GISSI II revealed no survival advantage of heparin plus streptokinase in acute MI compared with streptokinase alone.

ISIS II revealed that dihydropyridine calcium antagonists were associated with increased cardiovascular risk after MI.

Dipyridamole does not reduce risk.

A newly discovered pansystolic murmur may signify acquired mitral regurgitation (MR) or ventricular septal defect (VSD).

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 7 mins 35 secs

Question: 87 of 100

Which of the following features would be expected in acute tubular necrosis?

(Please select 1 option)

- Creatinine clearance would be expected to be normal one year after the initial insult
- Heavy proteinuria on urinalysis
- Red cell casts on urinalysis
- Urine plasma osmolality ratio is more than 1:1
- Urine sodium concentration greater than 30 mmol/l

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 9 mins 43 secs

Question: 87 of 100

Which of the following features would be expected in acute tubular necrosis?

(Please select 1 option)

○	Creatinine clearance would be expected to be normal one year after the initial insult
○	Heavy proteinuria on urinalysis
◉	Red cell casts on urinalysis ✕ Incorrect answer selected
○	Urine plasma osmolality ratio is more than 1:1
○	Urine sodium concentration greater than 30 mmol/l ← This is the correct answer

Red cell casts suggest nephritis and normalisation of the creatinine clearance occurs in only 40% of cases one year later.

Proteinuria, usually mild, is common with granular casts found on urinalysis.

The urine sodium concentration is typically above 30 mmol/l and osmolality ratio <1:1.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 9 mins 43 secs

Question: 88 of 100

Which of the following would be expected features of a left posterior cerebral artery occlusion?

(Please select 1 option)

- A right homonymous hemianopia
- Decerebrate state
- Internuclear ophthalmoplegia
- Pure aphasia (i.e. without alexia)
- Wernicke's aphasia

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 17 mins 31 secs

Question: 88 of 100

Which of the following would be expected features of a left posterior cerebral artery occlusion?

(Please select 1 option)

◉	A right homonymous hemianopia ✓ Correct
○	Decerebrate state
○	Internuclear ophthalmoplegia
○	Pure aphasia (i.e. without alexia)
○	Wernicke's aphasia

Internuclear ophthalmoplegia is typical of multiple sclerosis.

Wernicke's aphasia and Pure aphasia (i.e. without alexia) are middle cerebral artery.

Decerebrate state is most likely a pontine lesion.

Other possible findings in posterior left cerebral artery occlusion are:

- cortical blindness
- visual hallucinations
- thalamic syndrome
- Claude's and Weber's syndromes.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 17 mins 31 secs

Question: 89 of 100

A 70-year-old man was admitted with pallor, light-headedness and loss of energy.

On the day prior to admission he had reported loose dark stools.

Examination revealed a pulse of 110 per minute and a blood pressure of 106/70 mmHg.

Investigations revealed:

Haemoglobin	7.2 g/dl	(14-18)
MCV	72 fl	(80-96)
White cell count	11.3 x 10^9/l	(4-11)
Platelet count	480 x 10^9/l	(150-400)

What is the most appropriate next step in his management?

(Please select 1 option)

- ○ Barium meal
- ○ Blood transfusion
- ○ Endoscopy
- ○ Parenteral iron infusion
- ○ Proton pump inhibitor therapy

Platelet count	480 x 10^9/l	(150-400)

What is the most appropriate next step in his management?

(Please select 1 option)

○	Barium meal
○	Blood transfusion ← This is the correct answer
◉	Endoscopy ✕ Incorrect answer selected
○	Parenteral iron infusion
○	Proton pump inhibitor therapy

There is only one answer here and that is blood transfusion.

He has clearly had a major gastrointestinal (GI) bleed since he presents with symptoms of shock with a high resting heart rate and lowish blood pressure the day after what sounds like melaena. What is more he has a significant microcytic anaemia.

He should be resuscitated with blood transfusion and then sent for upper GI endoscopy.

A barium meal will not help a bleeding vessel.

Parenteral iron is for chronic anaemia not acute bleeds and proton pump inhibitors, although widely used, have no supportive evidence and are nowhere near as important as giving blood to this man.

Work Smart Session - MRCP Part 1

Time taken: 35 mins 41 secs

Question: 8 of 100

A 23-year-old man with known peanut allergy presented to the Emergency Department with anaphylaxis. He has a swollen face and lips. His BP is 90/60 mmHg, pulse 110 bpm and he is wheezy.

Which of the following formulations of adrenaline should be given?

(Please select 1 option)

○	0.5 ml of 1:10000 adrenaline IM
◉	0.5 ml of 1:1000 adrenaline IM ✓ Correct
○	5 ml of 1:1000 adrenaline IM
○	10 ml of 1:10000 adrenaline IV
○	Nebulised adrenaline

"For adults, a dose of 0.5 mL adrenaline 1:1000 solution (500 micrograms) should be administered intramuscularly, and repeated after about five minutes in the absence of clinical improvement or if deterioration occurs after the initial treatment especially if consciousness becomes - or remains - impaired as a result of hypotension. In some cases several doses may be needed, particularly if improvement is transient."
Resuscitation Council UK.

Adult EpiPen which allergy sufferers can carry with them contains 0.3 mg adrenaline in a 1:1000 dilution for intramuscular (IM) injection.

Work Smart Session - MRCP Part 1

Time taken: 35 mins 41 secs

Question: 9 of 100

A 55-year-old man presented to the emergency department with sudden breathlessness.

He is sweaty and obviously short of breath. He is a smoker with a past history of hypertension. There are crackles on inspiration at both his lung bases and his CXR shows upper lobe venous diversion and peri-hilar shadowing.

His ECG shows sinus tachycardia only and his cardiac enzymes, when they return the next day, are normal. His symptoms resolved quickly with oxygen and furosemide.

Which of the following conditions is the most likely explanation of this presentation?

(Please select 1 option)

- ○ Hypertrophic obstructive cardiomyopathy
- ○ Myocardial infarction
- ○ Phaeochromocytoma
- ○ Pulmonary embolism
- ○ Renal artery stenosis

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 21 mins 28 secs

Question: 90 of 100

A 16-year-old girl with obesity was referred with abdominal swelling and mild ankle oedema.

On examination the blood pressure was 140/90 mmHg.

Investigations revealed:

Haemoglobin	10.5 g/dl	(11.5-16.5)
Serum biochemistry	Normal	
Serum albumin	34 g/l	(37-49)
Urine dipstick	Proteinuria +	

Which is the most appropriate investigation that you would request next for this patient?

(Please select 1 option)

- 24 hour urinary protein estimation
- Abdominal ultrasound
- Plasma protein electrophoresis
- Urinary albumin: creatinine ratio
- Urinary B-human chorionic gonadotrophin test (B-HCG)

Submit answer | Skip question | Tag Question | Remove question

Haemoglobin	10.5 g/dl	(11.5-16.5)
Serum biochemistry	Normal	
Serum albumin	34 g/l	(37-49)
Urine dipstick	Proteinuria +	

Which is the most appropriate investigation that you would request next for this patient?

(Please select 1 option)

○	24 hour urinary protein estimation
◉	Abdominal ultrasound ✕ Incorrect answer selected
○	Plasma protein electrophoresis
○	Urinary albumin: creatinine ratio
○	Urinary B-human chorionic gonadotrophin test (B-HCG) ← This is the correct answer

This young girl has been 'gaining weight', has abdominal swelling and ankle oedema. She is hypertensive and has a mild anaemia with proteinuria.

These signs should 'ring a bell' suggesting a concealed pregnancy with pre-eclampsia.

The most relevant investigation would be a pregnancy test - urinary B-HCG.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 24 mins 31 secs

Question: 91 of 100

A 70-year-old female is admitted 12 hours after taking an overdose of aspirin.

Investigations revealed:

Serum sodium	138 mmol/l	(137-144)
Serum potassium	5.9 mmol/l	(3.5-4.9)
Serum bicarbonate	14 mmol/l	(20-28)
Serum urea	18.1 mmol/l	(2.5-7.5)
Serum creatinine	238 mol/l	(60-110)
Serum salicylate	1120 mg/l	(8)

What is the most appropriate treatment of this patient?

(Please select 1 option)

- Haemodialysis
- Haemofiltration
- Intravenous sodium bicarbonate
- Peritoneal dialysis
- Urine alkalinisation

Submit answer | Skip question | Tag Question | Remove question

Serum creatinine	238 mol/l	(60-110)
Serum salicylate	1120 mg/l	(8)

What is the most appropriate treatment of this patient?

(Please select 1 option)

- ◉ Haemodialysis ✓ Correct
- ○ Haemofiltration
- ○ Intravenous sodium bicarbonate
- ○ Peritoneal dialysis
- ○ Urine alkalinisation

This patient is at major risk of aspirin toxicity as reflected by the excessive aspirin concentration and appears to have developed acute renal failure - she is acidotic with an elevated potassium.

Bicarbonate is recommended as a supportive therapy but in this patient, haemodialysis is the treatment of choice. The latter is advised when the plasma-salicylate concentration is greater than 700 mg/litre (5.1 mmol/litre) or in the presence of severe metabolic acidosis as recommended within the BNF poisons section.

There is nothing wrong with haemofiltration it just removes the toxin more slowly.

Read more (very detailed) about haemofiltration vs. haemodialysis in poisoning (pdf).

Question: 92 of 100

A 24-year-old man presented twelve hours after an overdose of dihydrocodeine 1.2 g and paracetamol 30 g.

He had pinpoint pupils, a Glasgow coma scale (GCS) score of 14 and a blood pressure of 100/60 mmHg.

Which one of the following is the most appropriate management?

(Please select 1 option)

○	500ml of 10% glucose intravenously over four hours.
○	Intravenous flumazenil.
◉	Intravenous N-acetylcysteine. ✓ Correct
○	Intravenous naloxone.
○	Oral activated charcoal.

This patient's GCS is reasonable and the opiate-like effects seem minimal (no evidence of respiratory depression).

However, this patient has received a hefty dose of paracetamol conferring a high risk of hepatic toxicity. The 12 hour delay makes the absorptive effects of charcoal limited and although it would be useful as gastric emptying may be delayed it is not as important in this patient as the paracetamol antidote.

Even though the paracetamol level is not provided, he should be treated with N-acetylcysteine without delay.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 30 mins 32 secs

Question: 93 of 100

A 44-year-old male with Child's grade C cirrhosis presented with haematemesis.

Which one of the following drugs, administered intravenously, would be the most appropriate, immediate treatment?

(Please select 1 option)

○	Isosorbide dinitrate
○	Omeprazole
○	Propranolol
○	Somatostatin
○	Tranexamic acid

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 44-year-old male with Child's grade C cirrhosis presented with haematemesis.

Which one of the following drugs, administered intravenously, would be the most appropriate, immediate treatment?

(Please select 1 option)

○	Isosorbide dinitrate
○	Omeprazole
○	Propranolol
◉	Somatostatin ✓ Correct
○	Tranexamic acid

The suggestion is that this patient is at particularly high risk of oesophageal varices.

Child's classification of cirrhosis is a points scale, based upon ascites/bilirubin etcetera, reflecting prognosis. The grades depend on the points scored from A-C, with C reflecting greatest risk.

Somatostatin acts to reduce portal pressures and has been demonstrated to be as effective as endoscopy at controlling variceal bleeding in the acute setting.

Beta-blockers can be used as oral prophylaxis for oesophageal varices.

Intravenous omeprazole has also been shown to be effective in reducing mortality in gastrointestingal haemorrhage of any cause (NEJM 2002) but somatostatin may be expected to be superior for the above patient.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 34 mins 2 secs

Question: 94 of 100

A 22-year-old woman complains of haemoptysis, abdominal pains and pyrexia for a month.

She is admitted to hospital and found to be apyrexial and not distressed. There are numerous crusted, linear lesions on her forearms.

What is the most likely diagnosis?

(Please select 1 option)

○	Acute intermittent porphyria
◉	Factitious disorder ✓ Correct
○	Systemic lupus erythematosus
○	TB
○	Wegener's granulomatosis

The history is very vague and the patient has no clinical features other than a rash which sounds typical of dermatitis artifacta.

The crusted lesions on the forearms suggest artefacta as this is the most typical site for these lesions.

Porphyria may be expected to have vesicles on sun exposed regions, face, arms and legs.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 35 mins 40 secs

Question: 97 of 100

Which of the following is currently recommended as the drug of choice in treating refractory ventricular fibrillation or pulseless ventricular tachycardia?

(Please select 1 option)

- Adenosine
- Amiodarone
- Bretylium
- Lidocaine
- Magnesium

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 36 mins 20 secs

Question: 97 of 100

Which of the following is currently recommended as the drug of choice in treating refractory ventricular fibrillation or pulseless ventricular tachycardia?

(Please select 1 option)

○	Adenosine
○	Amiodarone ← This is the correct answer
○	Bretylium
○	Lidocaine
◉	Magnesium ✕ Incorrect answer selected

300 mg of amiodarone made up to 20 ml with 5% dextrose given as an intravenous bolus is the drug of choice.

100 mg of lidocaine may be given intravenously when amiodarone is unavailable.

Historically 5 mg/Kg of bretylium was given, but it is no longer recommended.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 36 mins 20 secs

Question: 98 of 100

In adult basic life support the correct ratio of chest compressions to ventilations is:

(Please select 1 option)

○	5 to 1
○	8 to 1
○	10 to 1
○	15 to 2
○	30 to 2

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 36 mins 47 secs

Question: 98 of 100

In adult basic life support the correct ratio of chest compressions to ventilations is:

(Please select 1 option)

○	5 to 1
○	8 to 1
○	10 to 1
○	15 to 2
◉	30 to 2 ✓ Correct

15 compressions to two breaths was the recommended ratio regardless of the number of rescuers performing basic life support, but the recent guidelines now suggest 30:2.

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 36 mins 47 secs

Question: 99 of 100

In most cardiac arrest situations 1mg of adrenaline (epinephrine) is given intravenously every three minutes.

What is the correct volume and concentration of the adrenaline?

(Please select 1 option)

○	0.1 ml of 1 in 100
○	1 ml of 1 in 1000
○	10 ml of 1 in 1000
○	1 ml of 1 in 10,000
○	10 ml of 1 in 10,000

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 5 hrs 37 mins 17 secs

Question: 99 of 100

In most cardiac arrest situations 1mg of adrenaline (epinephrine) is given intravenously every three minutes.

What is the correct volume and concentration of the adrenaline?

(Please select 1 option)

○	0.1 ml of 1 in 100
◉	1 ml of 1 in 1000 ✕ Incorrect answer selected
○	10 ml of 1 in 1000
○	1 ml of 1 in 10,000
○	10 ml of 1 in 10,000 ← This is the correct answer

A 1 mg dose of adrenaline (epinephrine) would be administered with 0.1 ml of 1 in 100, 1 ml of 1 in 1000 and 10 ml of 1 in 10,000.

However, 10 ml of 1 in 10,000 is the recommended dose and concentration and is considered the optimum volume of adrenaline during cardiac arrest, and is recommended by the UK Research Council.

Question: 9 of 100

A 55-year-old man presented to the emergency department with sudden breathlessness.

He is sweaty and obviously short of breath. He is a smoker with a past history of hypertension. There are crackles on inspiration at both his lung bases and his CXR shows upper lobe venous diversion and peri-hilar shadowing.

His ECG shows sinus tachycardia only and his cardiac enzymes, when they return the next day, are normal. His symptoms resolved quickly with oxygen and furosemide.

Which of the following conditions is the most likely explanation of this presentation?

(Please select 1 option)

○	Hypertrophic obstructive cardiomyopathy
○	Myocardial infarction
○	Phaeochromocytoma
◉	Pulmonary embolism ✕ Incorrect answer selected
○	Renal artery stenosis ← This is the correct answer

Flash pulmonary oedema in someone with a history of hypertension, especially those suspected of being arteriopaths such as smokers, should raise the possibility of renal artery stenosis.

NPIS Edinburgh

Background

- The physicochemical basis for dialysis was first described by the Scottish chemist Thomas Graham in 1854.
- In his paper "On Osmotic Force" he described the movements of various solutes of differing concentrations through a membrane he had fashioned from an ox bladder.

NPIS Edinburgh

Background

- The first artificial kidney was created in 1913,
- First one to be successful developed 1943.
- This involved a rotating drum of spiral-shaped cellophane tubing which contained a patient's blood, immersed in a dialysate bath.
- A parallel plate dialyzer was developed in 1948, and the first hollow fiber kidney was created in 1965.

Vol. 253 No. 6 THERAPY FOR SALICYLISM — SCHREINER ET AL.

SPECIFIC THERAPY FOR SALICYLISM*

GEORGE E. SCHREINER, M.D.,† LEONARD B. BERGAN, M.D.,‡ JOHN GRIFFIN, M.D.,§ AND JEAN PETZ, M.D.¶

- 1957
- 2 cases of salicylate poisoning treated by haemodialysis

NPIS Edinburgh

First use of haemodialysis in aspirin poisoning,1957

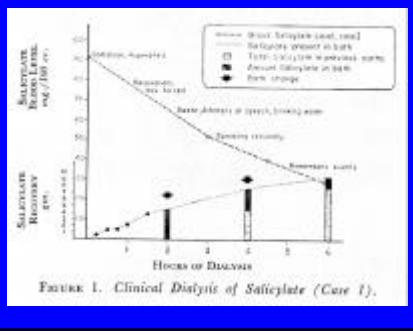

FIGURE 1. *Clinical Dialysis of Salicylate (Case 1).*

Twin-coil artificial kidney, 1960s

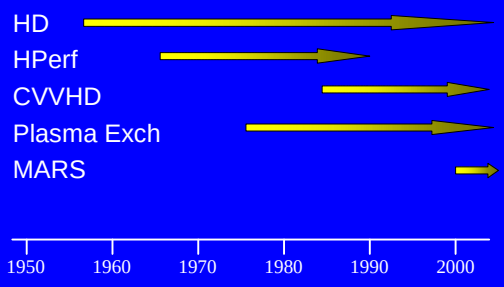
Extracorporeal elimination techniques

- Haemodialysis (HD)
- Haemofiltration (HF)
- Haemodiafiltration (HDF)

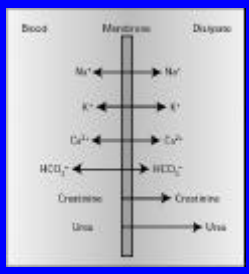
- *Haemoperfusion (HP)*
- *Plasma exchange (PE)*
- *Molecular adsorbent recirculating system (MARS)*

NPIS Edinburgh

Perfusion elimination techniques: History

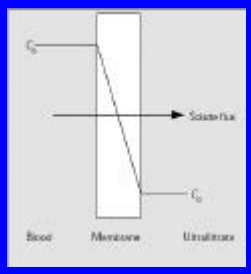


Dialysis



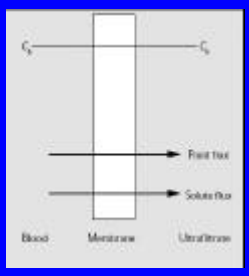
- dialysis is the process of separating elements in a solution by diffusion across a semi-permeable membrane, down a concentration gradient
- this is the principal process for removing small molecules and for repletion of the bicarbonate deficit of metabolic acidosis

Haemodialysis (HD)



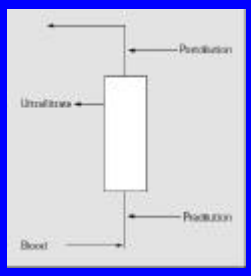
- molecules small enough to pass through the dialysis membrane diffuse down a concentration gradient, from a higher plasma concentration (C_b) to a lower dialysate concentration (C_d)

Haemofiltration (HF)



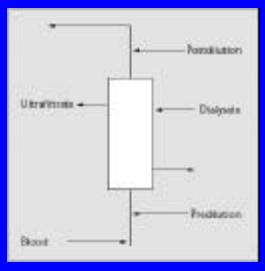
- haemofiltration achieves molecular clearance by convective transport (the solvent drag effect) through the membrane, with pore dimensions exceeding those in conventional dialysis treatment, by removing plasma water and toxin.

Fluid replacement in haemofiltration



- molecular clearance is achieved by removing large volumes of plasma water (contains dissolved solutes)
- the removed fluid must be replaced and is infused into the extracorporeal circuit after the blood leaves the filter (postdilution)

Haemodiafiltration (HDF)



- diffusive transport is added to haemofiltration to augment the clearance of solutes (usually small molecules)
- solute clearance is accomplished by circulating dialysate in the dialysate-ultrafiltrate compartment

Continuous renal replacement therapies

- CAVH, Continuous arterio- venous haemodialysis
- CVVH, Continuous veno- venous haemodialysis
- CVVHDF, Continuous veno- venous haemodialysis filtration

NPIS Edinburgh

Continuous renal replacement therapies: CAVH, CVVH, CVVHDF

- These methods allow continuous removal of smaller volume of fluid, and toxins, at low blood flow rates.
- Larger molecules up to 50 000 daltons may be removed in filtration.
- Techniques are better tolerated in haemodynamically unstable patients.
- In general flow, and thus extraction rates, lower than traditional techniques.

NPIS Edinburgh

High-performance haemodialysis

- High-efficiency dialysis – arbitrarily defined by urea clearance of >210 ml/min *(reflects capacity to remove urea)*
- High-flux dialysis – arbitrarily defined as a beta$_2$-microglobulin clearance of > 20 ml/min, is achieved using a high flux membrane *(reflects capacity to remove larger molecules)*

NPIS Edinburgh

High-efficiency and high-flux haemodialysis, continuous therapies

- These new modalities shorten the time of haemodialysis and have ability to remove "middle" molecules.
- The use of high-efficiency and high-flux membranes and continuous therapies steadily has increased over the past 10 years.
- Since reports of their effectiveness in renal replacement therapy, they have also been used for the treatment of poisoning.

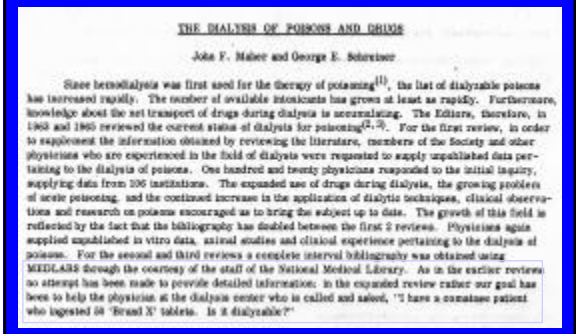
Haemodialysis or Haemofiltration?

Which agents?

Which techniques?

Which assessments?

NPIS
Edinburgh



THE DIALYSIS OF POISONS AND DRUGS

John F. Maher and George E. Schreiner

Since hemodialysis was first used for the therapy of poisoning[1], the list of dialyzable poisons has increased rapidly. The number of available intoxicants has grown at least as rapidly. Furthermore, knowledge about the net transport of drugs during dialysis is accumulating. The Editors, therefore, in 1963 and 1965 reviewed the current status of dialysis for poisoning[2, 3]. For the first review, in order to supplement the information obtained by reviewing the literature, members of the Society and other physicians who are experienced in the field of dialysis were requested to supply unpublished data pertaining to the dialysis of poisons. One hundred and twenty physicians responded to the initial inquiry, supplying data from 106 institutions. The expanded use of drugs during dialysis, the growing problem of acute poisoning, and the continued increase in the application of dialytic techniques, clinical observations and research on poisons encouraged us to bring the subject up to date. The growth of this field is reflected by the fact that the bibliography has doubled between the first 2 reviews. Physicians again supplied unpublished in vitro data, animal studies and clinical experience pertaining to the dialysis of poisons. For the second and third reviews a complete interval bibliography was obtained using MEDLARS through the courtesy of the staff of the National Medical Library. As in the earlier reviews no attempt has been made to provide detailed information; in the expanded review rather our goal has been to help the physician at the dialysis center who is called and asked, "I have a comatose patient who ingested 50 'Brand X' tablets. Is it dialyzable?"

Maher JF and Schreiner GE. Trans Amer Soc Artific Int Organs 1967;13:369-93.

Haemodialysis or Haemofiltration?

Which technique?

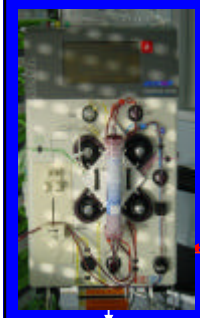
NPIS Edinburgh

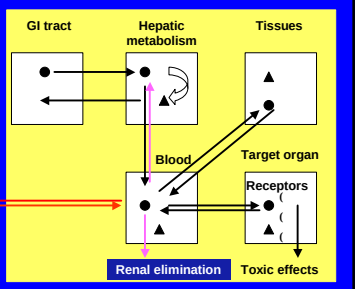
Evaluation of elimination techniques

- **Efficacy**
  - Does the technique increase the elimination of a given poison ?
- **Clinical Effectiveness**
  - Does the technique work in patients ?
- **Efficiency**
  - Does the technique compare favourably with other alternatives in terms of consequences (morbidity, mortality, adverse effects…) and costs ?

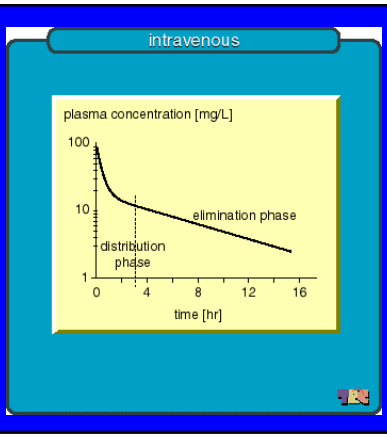
NPIS Edinburgh

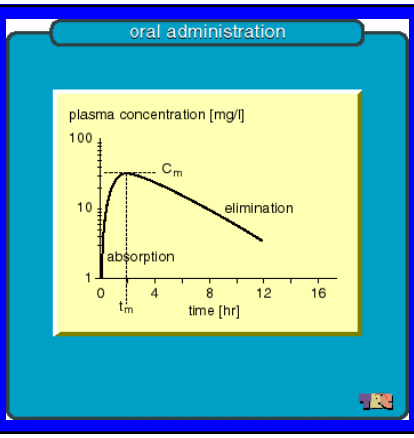
The kinetic approach





Elimination by the procedure



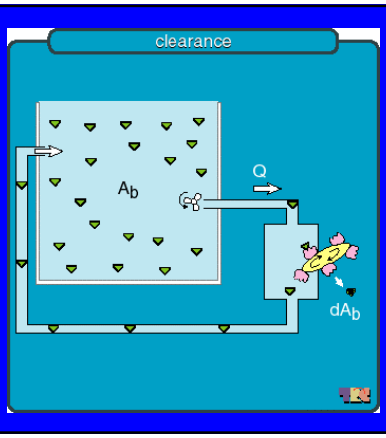


The kinetic approach: which parameters?

- **Plasma concentration** (units: mass/volume)
  = Amount bioavailable (mg)
  VD (l/kg) x weight (kg)

- **Plasma half-life** (units: time)
  = 0.693
  K el

- **Total clearance** (units: volume/time)
  = 0.693 x VD (ml) x weight(kg)
  T½ (min)



The kinetic approach: which parameters?

- Technique clearance (units: vol/time)

$$= \frac{(C_{in} - C_{out}) \times Q \text{ (ml/min)}}{C_{in}}$$

- Amount removed (units: mass)

$= C_{in}$ (mg/l) x Cl_{el} (ml/min) x time (min)

The kinetic approach

- The amount of drug removed depends on
  - plasma concentration
  - clearance achieved by the procedure
  - duration of the procedure

NPIS Edinburgh

The kinetic approach: criteria of efficacy ?

- T½ (during procedure) *vs* spontaneous T½
- Technique clearance *vs* *estimated* total clearance
- Amount recoverd *vs* *estimated* intrinsic elimination (renal, hepatic metabolism)

NPIS Edinburgh

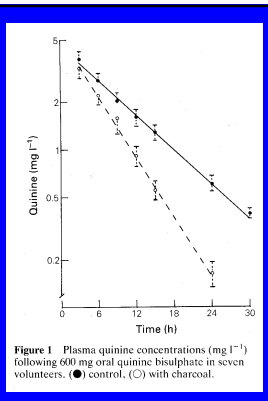


Figure 1 Plasma quinine concentrations (mg l^{-1}) following 600 mg oral quinine bisulphate in seven volunteers, (●) control, (○) with charcoal.

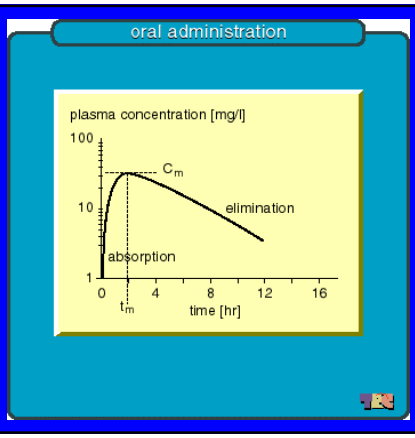
Lockey and Bateman, Br J Clin Pharmacol 1989;27:92-4.

The kinetic approach : pitfalls

- Dose estimate
- Role of continued absorption
- Decrease of plasma concentration may reflect clearance, absorption and distribution

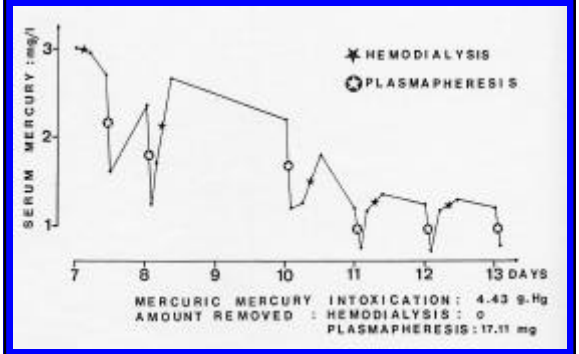
NPIS Edinburgh



The kinetic approach : pitfalls

- Over-estimation of procedure clearance
- Failure to assess procedure clearance *vs* Total clearance

NPIS Edinburgh



The kinetic approach

- Some drugs and poisons may be eliminated in a significant amount by elimination techniques

NPIS Edinburgh

Toxin removal by dialysis is determined by:

- Dialyzer conditions (blood flow rate, dialysate flow rate, dialyzer surface area, and pore structure of the chosen membrane)
- Toxicokinetic factors of the toxic substances
- Cardiovascular stability

NPIS Edinburgh

Hemodialysis: "ideal" toxin characteristics

low volume of distribution (<1 L/kg)
low endogenous clearance
a low molecular weight (<500 daltons)
high water solubility
? low protein binding

NPIS Edinburgh

Haemodialysis and poisoning

- To be clinically effective dialysis should improve the removal of a toxin in comparison to total body clearance

?? How much difference is needed

NPIS Edinburgh

Agents routinely dialyzed

lithium

methanol
ethylene glycol

salicylates

NPIS Edinburgh

Hemodialysis and poisoning

- early removal of toxic alcohols prevents toxicity from their toxic metabolites, which are also removed by hemodialysis
- the metabolic acidosis associated with methanol, ethylene glycol and salicylates is also corrected during hemodialysis

NPIS Edinburgh

The technical approach: conclusion

- Numerous drugs and poisons cross the dialysing membrane
- Clinical efficacy requires more than this

NPIS Edinburgh

Which criteria of efficacy ?

- clinical improvement
- decrease of the duration of poisoning
- decrease of severity, mortality, morbidity
- prevention of severe toxicity
  - ⇙ dependent on the kinetic-dynamic relationship

NPIS Edinburgh

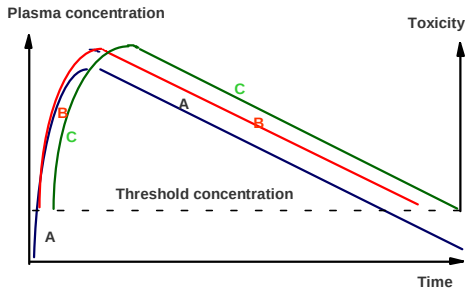
Enhanced elimination will only have a clinical benefit effect if :

- poisoning severity is related to the drug (or active metabolites) plasma concentration or body burden
- the prognosis depends on speed of elimination of the drug

NPIS Edinburgh

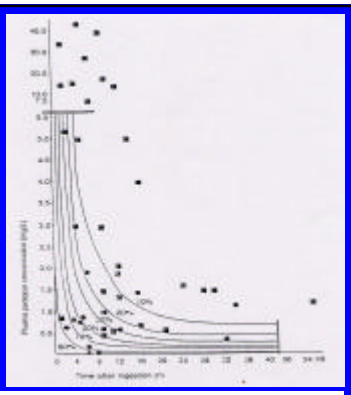
Kinetic-dynamic relationship : functional poison

(A = concentration ; B = toxicity ; C = delayed toxicity



Survivor (%) curves

- survivors
- non survivors



Hampson E. Failure of haemoperfusion and haemodialysis to prevent death in paraquat poisoning. A retrospective review of 42 patients. Med Toxicol, 1988; *3: 64-71*

The dynamic approach conclusion

- Clinical improvement
  =
  Efficacy of elimination technique
  - Clinical improvement without efficacy of the elimination technique
    - eg. : BZD, TCA…
  - Efficacy of the elimination technique without clinical improvement
    - eg. : paraquat, metals…

Lithium poisoning

- 49-old-year F , 21 g of lithium carbonate, acute/chronic
- serum Li = 5.3 mmol/L 6 hr HD; Li = 2.4 mmol/L
- CVVHDF (72 h) ; Total lithium removed by CVVHD = 6.5 g
- mean clearance = 23 ml/min !!
- *Conclusion: .."In lithium poisoning patients requiring dialysis, CVVHDF also appears to be efficacious and better tolerated by hemodynamically unstable patients"..*

Beckmann U et al..Efficacy of continuous venovenous hemodialysis in the treatment of severe lithium toxicity. J Toxicol Clin Toxicol 2001; 39(4):393-397.

Lithium and CAVHF –CAVHD-CVVHDF

	HD	HF	CAVHDF	CVVHD
Clearance ml/min	80-120	16.6 (1L) 33.3 (2 L)	20 (1 L) 36.1 (2 L) 42.8 (4 L)	48-62

Lithium poisoning

- 1). chronic lithium poisoning, Li = 5.4 mmol/L
- 2,5 h HD with high flux membrane; Li = 2.3 mmol/L
- 32 h CVVHDF Li = 0.91 mmol/L

- 2). acute/chronic poisoning, Li = 4.81 mmol/L
- 4 h HD with high flux membrane; Li = 1.34 mmol/L
- 22 h CVVHDF Li = 0.81 mmol/L
- *Conclusion: .."successful treatment...shows that HD followed by CVVHDF can be a safe and effective approach to management of severe lithium intoxication in children"*

Meyer RJ et al. Hemodialysis followed by continuous hemofiltration for treatment of lithium intoxication in children. Am J Kidney Dis 2001; 37(5): 1044-1047.

Methanol poisoning

- 44-year-old M – 125 ml – 2 hours before admission
- at admission – 3 pts GCS, respiratory failure; pH – 6.8, HCO_3 4.8 mmol/l, osmolal gap – 79 mosm/kg, anion gap – 37 mmol/L
- methanol serum level – 130 mg/dl
- Treatment: sodium bicarbonate, ethanol, folic acid; 2 h after admission HD (high-efficiency dialyzer)

Peces R, Alvarez R.: Effectiveness of hemodialysis with high-flux polysulfone membrane in the treatment of life-threatening methanol intoxication. Nephron 2002; 90(2):216-218.

Methanol poisoning

- Results: 1 h after HD - conscious, extubated; with no neurological and visual sequelae (CT scan normal); no acidosis

- Conclusion: ...*"modern HD using a bicarbonate dialysate and high-efficiency dialyzer (high-flux polysulfone) allow excellent removal of methanol and its metabolites and rapid correction of fluid, electrolyte and acid-base abnormalities"..*

Methanol poisoning

- 3 patients with methanol poisoning
- Haemodialysis vs CVVHDF
- Clearance increased 3 fold by CVVHDF
- Clearance by HD was 3 fold greater than CVVHDF
- Conclusion: CVVHDF an option in cardiovascular instability

Kan et al. Nephrol Dial Transplant 2003;18:2665.

Salicylate poisoning

- 18-year-old F, 600 tabl of 325-mg aspirin (=195 g)
- salicylate level (2 h post ingestion) = 674 mg/L
  - 1st HD – 455 mg/L, 7.5 hrs later = 828 mg/L
  - 2nd HD – 799 mg/L,
  - 3rd HD – 410 mg/L
- CVVHDF (21.5 hrs) – undetectable
- WBI
- Conclusion: *.."continued absorption of aspirin, necessitating intervention with WBI and CVVHD.."*

Chase PB et al. Whole bowel irrigation, hemodialysis, and continuous venovenous hemodiafiltration in the successful treatment of severe salicylate poisoning: case report. Dial Transplat 2002;31(6):387-391.

Kinetics of valproate

Half-life: 9-21 hrs (mean 15 hrs)

VD : 0.1-0.4 l/kg

NPIS Edinburgh

Valproate poisoning

- 25-year-old F – unknown amount
- VPA concentration: > 1,200 mg/L
  - HD high-flux 4 hr
- K_{el} = 0.25 (HD); post HD 0.029
- $T_{1/2}$ = 2.74 (HD); post HD 23.4
- *Conclusion: .. "toxic concentration of valproic acid can be effectively reduced with high-flux HD without the addition of charcoal haemoperfusion".. NO CLEARANCE ESTIMATE*

Kane SL et al. High-flux hemodialysis without hemoperfusion is effective in acute valproic acid overdose. Ann Pharmacother 2000; 34(10):1146-1151.

Valproate poisoning

- 24-year-old M, 30 g of valproic acid (coma, ventilatory failure, hypotension, hyperammonemia) VPA 670 mg/L
- 1st high-flux HD (4 hrs): VPA – 210 mg/L
- Cl = 121 ml/min, amount recovered = 5.9 g
- 2nd HD (flow 130 ml/min for 10 hrs):
- Cl = 56 ml/min, amount recovered = 3.3 g
- calculated total amount present in the body = 17.9 g;
- total removed 15.5 g (9.2 g during HD)
- *Conclusion: High-flux haemodialysis was more effective than endogenous elimination*

Kielstein JT et al. Efficacy of high-flux hemodialysis in the treatment of valproic acid intoxication. J Toxicol Clin Toxicol 2003; 41(6):873-876.

Valproate poisoning

- 48-year-old F - 48 g of sodium valproate
- VPA concentration: 332 – 1402 mg/L
  - CVVHDF with high-flux membrane (8 hr)
  - HD low flux 4 hr
- K_{el} = 0.036 – 0.062 (CVVHDF) – 0.31 (HD)
- $T_{1/2}$ = 28.5, 16.1 (CVVHDF), 2.2 (HD) hr
- HD: extraction ratio = 0.48 → 0.16
- clearance = 90 ml/min → 56 ml/min
- *Conclusion: .. "superior drug clearance and clinical response may be obtain with haemodialysis compared with CVVHDF"..*

NPIS Edinburgh

Carbamazepine poisoning

- 18-month-old child
  peak concentration – 33 µg/ml
- High-efficiency HD (5 h) CBZ – 7.8 µg/ml
- $T_{1/2}$ before – 17.3 h
- $T_{1/2}$ during HEHD – 2.7 h
- $T_{1/2}$ after – 12.2 h
- *Conclusion: "..high-efficiency HD represents an alternative method for CBZ overdose*

BUT WHY DO IT??

Schuerer DJ et al. High-efficiency dialysis for carbamazepine overdose. J Toxicol Clin Toxicol 2000; 38(3):321-323.

Carbamazepine poisoning

- 31-year-old F – 4.5 g CBZ present in the body (calculated)
- CBZ concentration – 43 mg/L
- high-flux HD (3.5 h) CBZ – 33.8 mg/L
  - amount removed – 920 mg
- CHP (2h) – 20.9 ug/ml
  - amount removed – 950 mg
- *Conclusion: High-flux HD is as effective as CHP*

NO ASSESSMENT OF ENDOGENOUS CL

Kielstein JT et al. High-flux hemodialysis – an effective to hemoperfuison in the treatment of carbamazepine intoxication. Clin Nephrol 2002; 57(6):484-486.

Conclusions (1)

- High-performance HD seems to be more effective in the elimination of poisons - shorter time of procedure.
- HD delivers a more rapid elimination of toxin and a correction of associated acid-base and electrolyte disorders than continuous renal replacement therapy.

NPIS Edinburgh

Conclusions (2)

- Continuous techniques are more widely used in the intensive care unit, mainly due to better haemodynamic tolerance.
- Continuous techniques achieve clearances close to normal renal clearance.
- Continuous techniques should be considered in patients who are haemodymically unstable.

NPIS Edinburgh

The whole picture

- Dialysis efficacy depends on equipment clearance. High flow rates are therefore likely to be more effective.
- Patient cardiovascular stability is key to successful dialysis.
- Kinetic factors of the toxin are key to suitability of dialysis.
- Patient outcome is the key measure.

NPIS Edinburgh

Final Message

- Evaluate efficacy on kinetic and dynamic criteria
- Report inefficacy as well as success
- Evidence based medicine
  Role of the clinical toxicology societies position statements – guidelines

NPIS Edinburgh

Meningeal Signs: Kernig's Sign and Brudzinski's Sign

Series Editors and Contributing Authors:
Asif Saberi, MD
Saeed A. Syed, MD, MRCP

Meningitis, an inflammation of the meninges, is a life-threatening illness. If left untreated, meningitis has a high, almost absolute mortality and certain types of acute bacterial meningitis can be lethal within a matter of hours.[1] Therefore, early and accurate diagnosis and effective treatment are critical.

Several clinical signs facilitate the diagnosis of meningitis. Kernig's sign and Brudzinski's sign (**Sidebars**) are easy to elicit and can alert physicians to the precarious situation of a patient with meningitis. Both of these signs are thought to be caused by the irritation of motor nerve roots passing through inflamed meninges as the roots are brought under tension.

HISTORIC PERSPECTIVE

Meningitis has been recognized since antiquity.[2] As early as the 15th century BC, Hippocrates taught that "If during fever, the neck shalt have been suddenly twisted, the deglutition be rendered difficult without a tumor, it is a fatal sign."[3] Centuries later, King Henry II of France (1519–1559) is believed to have died from meningitis that he contracted after sustaining a scalp injury during sport.[4,5]

Meningitis was first described as a specific disease entity by British physician Thomas Willis (1621–1675) and Italian anatomist and pathologist Battista Morgagini (1682–1771).[6,7] The earliest recorded epidemic of meningitis on the American continent that might have been caused by bacterial meningitis was recorded at Medfield, MA, in 1806.[8] Autopsy data that showed pus between the patients' dura mater and pia mater substantiated bacterial meningitis as the causative factor.

MENINGEAL SIGNS

Kernig's Sign

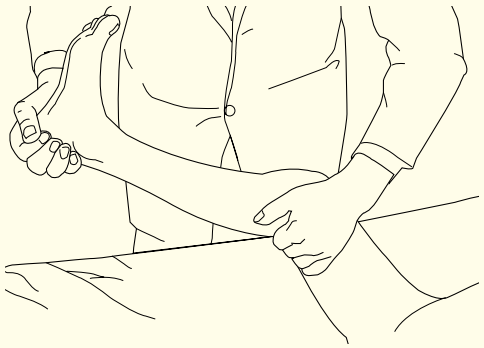
Russian physician Vladimir Kernig was born in Lepaia, Latvia, in 1840. Kernig received his medical degree in 1865 and joined the Obuhorsk Hospital in Saint Petersburgh, Russia, where he held a position until World War I.

Kernig first described the sign in the Saint Petersburgh Medizinische Wochenschrift in 1882.[9] During Kernig's examination, the patient was seated upright with hips and knees flexed. Kernig would then attempt to extend the patient's knee. He noted that, in patients with meningitis, he was unable to extend the knee beyond 135 degrees without causing pain.

Today, the maneuver is usually performed with the patient supine with hips and knees in flexion. Extension of the knees is attempted: the inability to extend the patient's knees beyond 135 degrees without causing pain constitutes a positive test for Kernig's sign.

KERNIG'S SIGN

Elicitation: Flexing the patient's hip 90 degrees then extending the patient's knee causes pain.



Drs. Saberi and Syed are Clinical Instructors, Department of Medicine, State University of New York at Buffalo, Buffalo, NY, and Staff Physicians, The Resource Center, Diagnostic and Treatment Outpatient Clinic, Dunkirk, NY.

BRUDZINSKI'S NECK SIGN

Elicitation: Flexing the patient's neck causes flexion of the patient's hips and knees.

Brudzinski's Sign

Jozef Brudzinski, a Polish physician in the early 20th century, became the dean of the University of Warsaw (Warsaw, Poland) and chief physician at the Hospital of Karl and Maria (Warsaw, Poland). By the beginning of the 20th century, Kernig's sign was well known and in widespread use in the medical community. However, Brudzinski's contribution to the understanding of meningeal signs is unique because Brudzinski used animal experiments to study the signs he elicited in patients with meningitis.[10,11]

Brudzinski's neck sign. Brudzinski actually described several different signs in patients with meningitis. Brudzinski's neck sign is most commonly recognized and is often simply referred to as *Brudzinski's sign*.

With the patient supine, the physician places one hand behind the patient's head and places the other hand on the patient's chest. The physician then raises the patient's head (with the hand behind the head) while the hand on the chest restrains the patient and prevents the patient from rising. Flexion of the patient's lower extremities (hips and knees) constitutes a positive sign. Brudzinski's neck sign has more sensitivity than Kernig's sign.[10]

Brudzinski's contralateral reflex sign. Brudzinski's contralateral reflex sign has two components: the identical and reciprocal contralateral reflux. The patient's hip and knee are passively flexed on one side; if the contralateral leg bends in reflex, identical contralateral reflex is demonstrated. Reciprocal contralateral reflex occurs when the leg that has flexed in response to the passive flexion of the contralateral hip and knee begins to extend passively.

SUMMARY

The importance of early recognition and treatment of meningitis cannot be overemphasized. With all the technological advances today, the medical community has yet to discover an economical, readily available screening test to supplant these easy-to-elicit physical signs. A positive result on these tests is an indication for the institution of antibiotic therapy, and treatment initiation need not be delayed until the performance of a lumbar puncture and receipt of the results. Overall mortality is still high, but with appropriate and timely treatment, most adult patients recover from meningitis and lead a normal life. Children recovering from meningitis occasionally experience sequelae such as hearing loss or cranial nerve deficit. These tests for meningitis are appropriately named to honor Kernig and Brudzinski, both of whom greatly contributed to medicine by facilitating the diagnosis of this life-threatening disease. **HP**

British Guideline on the Management of Asthma

A national clinical guideline

May 2008
revised June 2009

NHS Quality Improvement Scotland (NHS QIS) is committed to equality and diversity. This guideline has been assessed for its likely impact on the six equality groups defined by age, disability, gender, race, religion/belief, and sexual orientation.

For the full equality and diversity impact assessment report please see the "published guidelines" section of the SIGN website at **www.sign.ac.uk/guidelines/published/numlist.html**. The full report in paper form and/or alternative format is available on request from the NHS QIS Equality and Diversity Officer.

This document is produced from elemental chlorine-free material and is sourced from sustainable forests

KEY TO EVIDENCE STATEMENTS AND GRADES OF RECOMMENDATIONS

LEVELS OF EVIDENCE

1^{++}	High quality meta-analyses, systematic reviews of RCTs, or RCTs with a very low risk of bias
1^{+}	Well conducted meta-analyses, systematic reviews, or RCTs with a low risk of bias
1 -	Meta-analyses, systematic reviews, or RCTs with a high risk of bias
2^{++}	High quality systematic reviews of case control or cohort studies High quality case control or cohort studies with a very low risk of confounding or bias and a high probability that the relationship is causal
2^{+}	Well conducted case control or cohort studies with a low risk of confounding or bias and a moderate probability that the relationship is causal
2	Case control or cohort studies with a high risk of confounding or bias and a significant risk that the relationship is not causal
3	Non-analytic studies, eg case reports, case series
4	Expert opinion

GRADES OF RECOMMENDATION

Note: The grade of recommendation relates to the strength of the evidence on which the recommendation is based. It does not reflect the clinical importance of the recommendation.

A	At least one meta-analysis, systematic review, or RCT rated as 1^{++}, and directly applicable to the target population; or A body of evidence consisting principally of studies rated as 1^{+}, directly applicable to the target population, and demonstrating overall consistency of results
B	A body of evidence including studies rated as 2^{++}, directly applicable to the target population, and demonstrating overall consistency of results; *or* Extrapolated evidence from studies rated as 1^{++} or 1^{+}
C	A body of evidence including studies rated as 2^{+}, directly applicable to the target population and demonstrating overall consistency of results; *or* Extrapolated evidence from studies rated as 2^{++}
D	Evidence level 3 or 4; or Extrapolated evidence from studies rated as 2^{+}

GOOD PRACTICE POINTS

☑	Recommended best practice based on the clinical experience of the guideline development group.
❖	Audit point

1 Introduction

In 1999 the British Thoracic Society (BTS) and the Scottish Intercollegiate Guidelines Network (SIGN) agreed to jointly produce a comprehensive new asthma guideline, both having previously published guidance on asthma. The original BTS guideline dated back to 1990 and the SIGN guidelines to 1996. Both organisations recognised the need to develop the new guideline using explicitly evidence based methodology. The joint process was further strengthened by collaboration with Asthma UK, the Royal College of Physicians of London, the Royal College of Paediatrics and Child Health, the General Practice Airways Group, and the British Association of Accident and Emergency Medicine (now the College of Emergency Medicine). The outcome of these efforts was the British Guideline on the Management of Asthma published in 2003.[1]

The 2003 guideline was developed using SIGN methodology,[2] adapted for UK-wide use. Electronic literature searches extended to 1995, although some sections required searches back as far as 1966. The pharmacological management section utilised the North of England Asthma guideline to address some of the key questions on adult management.[3] The North of England guideline literature search covered a period from 1984 to December 1997, and SIGN augmented this with a search from 1997 onwards.

Since 2003 sections within the guideline have been updated annually and posted on both the BTS (www.brit-thoracic.org.uk) and SIGN (www.sign.ac.uk) websites. In 2004 the sections on pharmacological management, acute asthma and patient self management and compliance were revised. In 2005 sections on pharmacological management, inhaler devices, outcomes and audit and asthma in pregnancy were updated, and occupational asthma was rewritten with help from the British Occupational Health Research Foundation.

In 2006 the pharmacological management section was again updated. While the web-based alterations appeared successful, it was felt an appropriate time to consider producing a new paper-based version in which to consolidate the various yearly updates. In addition, since 2006, the guideline has had input from colleagues from Australia and New Zealand.

The 2008 guideline considered literature published up to March 2007. It contains a completely rewritten section on diagnosis for both adults and children; a section on special situations which includes occupational asthma, asthma in pregnancy and the new topic of difficult asthma; updated sections on pharmacological and non-pharmacological management; and amalgamated sections on patient education and compliance, and on organisation of care and audit. The 2009 revisions include updates to pharmacological management, the management of acute asthma and asthma in pregnancy. Update searches were conducted on inhaler devices but there was insufficient new evidence to change the existing recommendations. The annexes have also been amended to reflect current evidence. The timescale of the literature search for each section is given in Annex 1. It is hoped that this asthma guideline continues to serve as a basis for high quality management of both acute and chronic asthma and a stimulus for research into areas of management for which there is little evidence. Sections of the guideline will continue to be updated on the BTS and SIGN websites on an annual basis.

2009

1.1 STATEMENT OF INTENT

This guideline is not intended to be construed or to serve as a standard of care. Standards of care are determined on the basis of all clinical data available for an individual case and are subject to change as scientific knowledge and technology advance and patterns of care evolve. Adherence to guideline recommendations will not ensure a successful outcome in every case, nor should they be construed as including all proper methods of care or excluding other acceptable methods of care aimed at the same results. The ultimate judgement must be made by the appropriate healthcare professional(s) responsible for clinical decisions regarding a particular clinical procedure or treatment plan. This judgement should only be arrived at following discussion of the options with the patient, covering the diagnostic and treatment choices available. It is advised, however, that significant departures from the national guideline or any local guidelines derived from it should be fully documented in the patient's case notes at the time the relevant decision is taken.

2 Diagnosis

The diagnosis of asthma is a clinical one; there is no standardised definition of the type, severity or frequency of symptoms, nor of the findings on investigation. The absence of a gold standard definition means that it is not possible to make clear evidence based recommendations on how to make a diagnosis of asthma.

Central to all definitions is the presence of symptoms (more than one of wheeze, breathlessness, chest tightness, cough) and of variable airflow obstruction. More recent descriptions of asthma in children and in adults have included airway hyper-responsiveness and airway inflammation as components of the disease. How these features relate to each other, how they are best measured and how they contribute to the clinical manifestations of asthma, remains unclear.

Although there are many shared features in the diagnosis of asthma in children and in adults there are also important differences. The differential diagnosis, the natural history of wheezing illnesses, the ability to perform certain investigations and their diagnostic value, are all influenced by age.

2.1 DIAGNOSIS IN CHILDREN

Asthma in children causes recurrent respiratory symptoms of:

- wheezing
- cough
- difficulty breathing
- chest tightness.

Wheezing is one of a number of respiratory noises that occur in children. Parents often use "wheezing" as a non-specific label to describe any abnormal respiratory noise. It is important to distinguish wheezing – a continuous, high-pitched musical sound coming from the chest – from other respiratory noises, such as stridor or rattly breathing.[4]

There are many different causes of wheeze in childhood and different clinical patterns of wheezing can be recognised in children. In general, these patterns ("phenotypes") have been assigned retrospectively. They cannot reliably be distinguished when an individual child first presents with wheezing. In an individual child the pattern of symptoms may change as they grow older.

The commonest clinical pattern, especially in pre-school children and infants, is episodes of wheezing, cough and difficulty breathing associated with viral upper respiratory infections (colds), with no persisting symptoms. Most of these children will stop having recurrent chest symptoms by school age.

A minority of those who wheeze with viral infections in early life will go on to develop wheezing with other triggers so that they develop symptoms between acute episodes (interval symptoms) similar to older children with classical atopic asthma.[5-9] 2++

Children who have persisting or interval symptoms are most likely to benefit from therapeutic interventions.

2.1.1 MAKING A DIAGNOSIS IN CHILDREN

Initial clinical assessment

The diagnosis of asthma in children is based on recognising a characteristic pattern of episodic respiratory symptoms and signs *(see Table 1)* in the absence of an alternative explanation for them *(see Tables 2 and 3)*.

Table 1: Clinical features that increase the probability of asthma

More than one of the following symptoms: wheeze, cough, difficulty breathing, chest tightness, particularly if these symptoms:

- ◊ are frequent and recurrent[10-13]
- ◊ are worse at night and in the early morning[11,12,14]
- ◊ occur in response to, or are worse after, exercise or other triggers, such as exposure to pets, cold or damp air, or with emotions or laughter
- ◊ occur apart from colds[10]

- Personal history of atopic disorder[10,13,15]
- Family history of atopic disorder and/or asthma[10,16]
- Widespread wheeze heard on auscultation
- History of improvement in symptoms or lung function in response to adequate therapy

Table 2: Clinical features that lower the probability of asthma

- Symptoms with colds only, with no interval symptoms[10]
- Isolated cough in the absence of wheeze or difficulty breathing[17]
- History of moist cough[18]
- Prominent dizziness, light-headedness, peripheral tingling
- Repeatedly normal physical examination of chest when symptomatic
- Normal peak expiratory flow (PEF) or spirometry when symptomatic
- No response to a trial of asthma therapy[19]
- Clinical features pointing to alternative diagnosis *(see Table 3)*

Several factors are associated with a high (or low) risk of developing persisting wheezing or asthma through childhood.[15,20] The presence of these factors increases the probability that a child with respiratory symptoms will have asthma.

These factors include:

Age at presentation

The natural history of wheeze is dependent on age at first presentation. In general, the earlier the onset of wheeze, the better the prognosis. Cohort studies show a "break point" at around two years; most children who present before this age become asymptomatic by mid-childhood.[6,8,9,21] Co-existent atopy is a risk factor for persistence of wheeze independent of age of presentation. | 2^{++}

Sex

Male sex is a risk factor for asthma in pre-pubertal children. Female sex is a risk factor for the persistence of asthma in the transition from childhood to adulthood.[22,23] Boys with asthma are more likely to "grow out" of their asthma during adolescence than girls.[10,21,22,24-37]

Severity and frequency of previous wheezing episodes

Frequent or severe episodes of wheezing in childhood are associated with recurrent wheeze that persists into adolescence.[5,8,13,16,21,26,38,39] | 2^{++}

Coexistence of atopic disease

A history of other atopic conditions such as eczema and rhinitis increases the probability of asthma. Positive tests for atopy in a wheezing child also increase the likelihood of asthma. A raised specific IgE to wheat, egg white, or inhalant allergens such as house dust mite and cat dander, predicts later childhood asthma.[40,41] 2++

Other markers of allergic disease at presentation, such as positive skin prick tests and a raised blood eosinophil count, are related to the severity of current asthma and persistence through childhood.

Family history of atopy

A family history of atopy is the most clearly defined risk factor for atopy and asthma in children. The strongest association is with maternal atopy, which is an important risk factor for the childhood onset of asthma and for recurrent wheezing that persists throughout childhood.[6,34,37,42,43] 2++

Abnormal lung function

Persistent reductions in baseline airway function and increased airway responsiveness during childhood are associated with having asthma in adult life.[23] 3

Table 3: Clinical clues to alternative diagnoses in wheezy children (features not commonly found in children with asthma)

Perinatal and family history	**Possible diagnosis**
Symptoms present from birth or perinatal lung problem	Cystic fibrosis; chronic lung disease of prematurity; ciliary dyskinesia; developmental anomaly
Family history of unusual chest disease	Cystic fibrosis; neuromuscular disorder
Severe upper respiratory tract disease	Defect of host defence; ciliary dyskinesia
Symptoms and signs	
Persistent moist cough[18]	Cystic fibrosis; bronchiectasis; protracted bronchitis; recurrent aspiration; host defence disorder; ciliary dyskinesia
Excessive vomiting	Gastro-oesophageal reflux (± aspiration)
Dysphagia	Swallowing problems (± aspiration)
Breathlessness with light-headedness and peripheral tingling	Hyperventilation/panic attacks
Inspiratory stridor	Tracheal or laryngeal disorder
Abnormal voice or cry	Laryngeal problem
Focal signs in chest	Developmental anomaly; post-infective syndrome; bronchiectasis; tuberculosis
Finger clubbing	Cystic fibrosis; bronchiectasis
Failure to thrive	Cystic fibrosis; host defence disorder; gastro-oesophageal reflux
Investigations	
Focal or persistent radiological changes	Developmental anomaly; cystic fibrosis; post-infective disorder; recurrent aspiration; inhaled foreign body; bronchiectasis; tuberculosis

Case detection studies have used symptom questionnaires to screen for asthma in school-age children. A small number of questions - about current symptoms, their relation to exercise and their occurrence at night has been sufficient to detect asthma relatively efficiently.[11,12,14,44] The addition of spirometry[11,44] or bronchial hyper-responsiveness testing[45] to these questionnaires adds little to making a diagnosis of asthma in children. 2+

B **Focus the initial assessment in children suspected of having asthma on:**
- **presence of key features in the history and examination**
- **careful consideration of alternative diagnoses.**

☑ Record the basis on which a diagnosis of asthma is suspected.

2.1.2 ASSESSING THE PROBABLITY OF A DIAGNOSIS OF ASTHMA

Based on the initial clinical assessment it should be possible to determine the probability of a diagnosis of asthma.

With a thorough history and examination, an individual child can usually be classed into one of three groups *(see Figure 1)*:

- **high probability** – diagnosis of asthma likely
- **low probability** – diagnosis other than asthma likely
- **intermediate probability** – diagnosis uncertain.

2.1.3 HIGH PROBABILITY OF ASTHMA

In children with a high probability of asthma based on the initial assessment, move straight to a diagnostic trial of treatment. The initial choice of treatment will be based on an assessment of the degree of asthma severity *(see section 4)*.

The clinical response to treatment should be reassessed within 2-3 months. In this group, reserve more detailed investigations for those whose response to treatment is poor or those with severe disease.[19]

☑ In children with a high probability of asthma:
- start a trial of treatment
- review and assess response
- reserve further testing for those with a poor response.

2.1.4 LOW PROBABILITY OF ASTHMA

Where symptoms, signs or initial investigations suggest that a diagnosis of asthma is unlikely, *(see Table 2)*, or they point to an alternative diagnosis *(see Table 3)*, consider further investigations. This may require referral for specialist assessment *(see Table 4)*.

Reconsider a diagnosis of asthma in those who do not respond to specific treatments.

☑ In children with a low probability of asthma, consider more detailed investigation and specialist referral.

2.1.5 INTERMEDIATE PROBABILITY OF ASTHMA

In some children, and particularly those below the age of four to five, there is insufficient evidence at the first consultation to make a firm diagnosis of asthma, but no features to suggest an alternative diagnosis. There are several possible approaches to reaching a diagnosis in this group. Which approach is taken will be influenced by the frequency and severity of the symptoms.

These approaches include:

Watchful waiting with review

In children with mild, intermittent wheeze and other respiratory symptoms which occur only with viral upper respiratory infections (colds), it is often reasonable to give no specific treatment and to plan a review of the child after an interval agreed with the parents/carers.

Trial of treatment with review

The choice of treatment (for example, inhaled bronchodilators or corticosteroids) depends on the severity and frequency of symptoms. Although a trial of therapy with inhaled or oral corticosteroids is widely used to help make a diagnosis of asthma, there is little objective evidence to support this approach in children with recurrent wheeze.

It can be difficult to assess the response to treatment as an improvement in symptoms or lung function may be due to spontaneous remission. If it is unclear whether a child has improved, careful observation during a trial of withdrawing the treatment may clarify whether a response to asthma therapy has occurred.

Spirometry and reversibility testing

In children, as in adults, tests of airflow obstruction, airway responsiveness and airway inflammation may provide support for a diagnosis of asthma.[12,44] However, normal results on testing, especially if performed when the child is asymptomatic, do not exclude a diagnosis of asthma.[46] Abnormal results may be seen in children with other respiratory diseases. Measuring lung function in young children is difficult and requires techniques which are not widely available. 2+

Above five years of age, conventional lung function testing is possible in most children in most settings. This includes measures of airway obstruction (spirometry and peak flow), reversibility with bronchodilators, and airway hyper-responsiveness.

The relationship between asthma symptoms and lung function tests including bronchodilator reversibility is complex. Asthma severity classified by symptoms and use of medicines correlates poorly with single measurements of forced expiratory volume in one second (FEV_1) and other spirometric indices: FEV_1 is often normal in children with persistent asthma.[46,47] Serial measures of peak flow variability and FEV_1 show poor concordance with disease activity and do not reliably rule the diagnosis of asthma in or out.[47] Measures of gas trapping (residual volume and the ratio of residual volume to total lung capacity, RV/TLC) may be superior to measurements of expiratory flow at detecting airways obstruction especially in asymptomatic children.[46,48] 2+

A significant increase in FEV_1 (>12% from baseline)[49] or PEF after bronchodilator indicates reversible airflow obstruction and supports the diagnosis of asthma. It is also predictive of a good response to inhaled corticosteroids.[50] However, an absent response to bronchodilators does not exclude asthma.[51] 2+ 3

Between 2-5 years of age, many children can perform several newer lung function tests that do not rely on their cooperation or the ability to perform a forced expiratory manoeuvre. In general, these tests have not been evaluated as diagnostic tests for asthma. There is often substantial overlap between the values in children with and without asthma.[52] Of the tests available, specific airways resistance (sRaw), impulse oscillometry (IOS), and measurements of residual volume (RV) appear the most promising.[53] While some of these tests have been useful in research, their role in clinical practice is uncertain.[48,53,54] Most have only been used in specialist centres and are not widely available elsewhere. It is often not practical to measure variable airway obstruction in children below the age of five. 2+

2.1.6 CHILDREN WITH AN INTERMEDIATE PROBABILITY OF ASTHMA AND EVIDENCE OF AIRWAY OBSTRUCTION

Asthma is the by far the commonest cause of airways obstruction on spirometry in children. Obstruction due to other disorders, or due to multiple causes, is much less common in children than in adults. Spirometry and other lung function tests, including tests of PEF variability,[47] lung volumes and airway responsiveness,[45] are poor at discriminating between children with asthma and those with obstruction due to other conditions.

☑ In children with an intermediate probability of asthma who can perform spirometry and have evidence of airways obstruction, assess the change in FEV_1 or PEF in response to an inhaled bronchodilator (reversibility) and/or the response to a trial of treatment for a specified period:

- if there is significant reversibility, or if a treatment trial is beneficial, a diagnosis of asthma is probable. Continue to treat as asthma, but aim to find the minimum effective dose of therapy. At a later point, consider a trial of reduction or withdrawal of treatment.
- if there is no significant reversibility, and a treatment trial is not beneficial, consider tests for alternative conditions *(see Table 3)*.

2.1.7 CHILDREN WITH AN INTERMEDIATE PROBABILITY OF ASTHMA WITHOUT EVIDENCE OF AIRWAY OBSTRUCTION

In this group, further investigations, including assessment of atopic status and bronchodilator responsiveness and if possible tests of airway responsiveness, should be considered *(see section 2.2.1)*. This is particularly so if there has been a poor response to a trial of treatment or if symptoms are severe. In these circumstances, referral for specialist assessment is indicated.

C **In children with an intermediate probability of asthma who can perform spirometry and have no evidence of airways obstruction:**

- **consider testing for atopic status, bronchodilator reversibility and, if possible, bronchial hyper-responsiveness using methacholine, exercise or mannitol.**
- **consider specialist referral.**

2.1.8 CHILDREN WITH AN INTERMEDIATE PROBABILITY OF ASTHMA WHO CANNOT PERFORM SPIROMETRY

Most children under five years and some older children cannot perform spirometry. In these children, offer a trial of treatment for a specific period. If there is clear evidence of clinical improvement, the treatment should be continued and they should be regarded as having asthma (it may be appropriate to consider a trial of withdrawal of treatment at a later stage). If the treatment trial is not beneficial, then consider tests for alternative conditions and referral for specialist assessment.

☑ In children with an intermediate probability of asthma who cannot perform spirometry, offer a trial of treatment for a specified period:

- if treatment is beneficial, treat as asthma and arrange a review
- if treatment is not beneficial, stop asthma treatment and consider tests for alternative conditions and specialist referral.

2.2 OTHER INVESTIGATIONS

2.2.1 TESTS OF AIRWAY HYPER-RESPONSIVENESS

The role of tests of airway responsiveness (airway hyper-reactivity) in the diagnosis of childhood asthma is unclear.[45,55] For example, a methacholine challenge test has a much lower sensitivity than symptoms in diagnosing asthma in children and only marginally increases the diagnostic accuracy after the symptom history is taken into account.[45] However, a negative methacholine test in children, which has a high negative predictive value, makes a diagnosis of asthma improbable.[55] Similarly, a negative response to an exercise challenge test is helpful in excluding asthma in children with exercise related breathlessness.[56] 3

2.2.2 TEST OF EOSINOPHILIC AIRWAY INFLAMMATION

Eosinophilic inflammation in children can be assessed non-invasively using induced sputum differential eosinophil count or exhaled nitric oxide concentrations (FE_{NO}).

Sputum induction is feasible in school age children.[57,58] Higher sputum eosinophil counts are associated with more marked airways obstruction and reversibility, greater asthma severity and atopy.[59] In children with newly diagnosed mild asthma, sputum eosinophilia is present and declines with inhaled steroid treatment.[58] Sputum induction is possible in approximately 75% of children tested, but it is technically demanding and time consuming and at present remains a research tool. 2^{++}

It is feasible to measure FE_{NO} in unsedated children from the age of 3-4 years.[60] A raised FE_{NO} is neither a sensitive nor a specific marker of asthma with overlap with children who do not have asthma.[61] FE_{NO} is closely linked with atopic status, age and height.[62,63] In some studies, FE_{NO} correlated better with atopic dermatitis and allergic rhinitis than with asthma. It is not closely linked with underlying lung function. FE_{NO} could not differentiate between groups once atopy was taken into account.[64] Home measurements of FE_{NO} have a highly variable relationship with other measures of disease activity and vary widely from day to day.[65] 2^{+}

At present, there is insufficient evidence to support a role for markers of eosinophilic inflammation in the diagnosis of asthma in children. They may have a role in assessing severity of disease or response to treatment.

2.2.3 TESTS OF ATOPY

Positive skin tests,[66] blood eosinophilia $\geq 4\%$[10], or a raised specific IgE to cat, dog or mite,[67,68] increase the probability of asthma in a child with wheeze, particularly in children over five years of age.[66] It is important to recognise that non-atopic wheezing is as frequent as atopic wheezing in school-age children.[69] 2^{++}

2.2.4 CHEST X-RAY

A study in primary care in children age 0-6 years concluded that a chest X-ray (CXR), in the absence of a clinical indication, need not be part of the initial diagnostic work up.[70]

☑ Reserve chest X-rays for children with severe disease or clinical clues suggesting other conditions.

2.3 SUMMARY

Focus the initial assessment of children suspected of having asthma on:

- presence of key features in the history and clinical examination
- careful consideration of alternative diagnoses.

Record the basis on which the diagnosis of asthma is suspected.

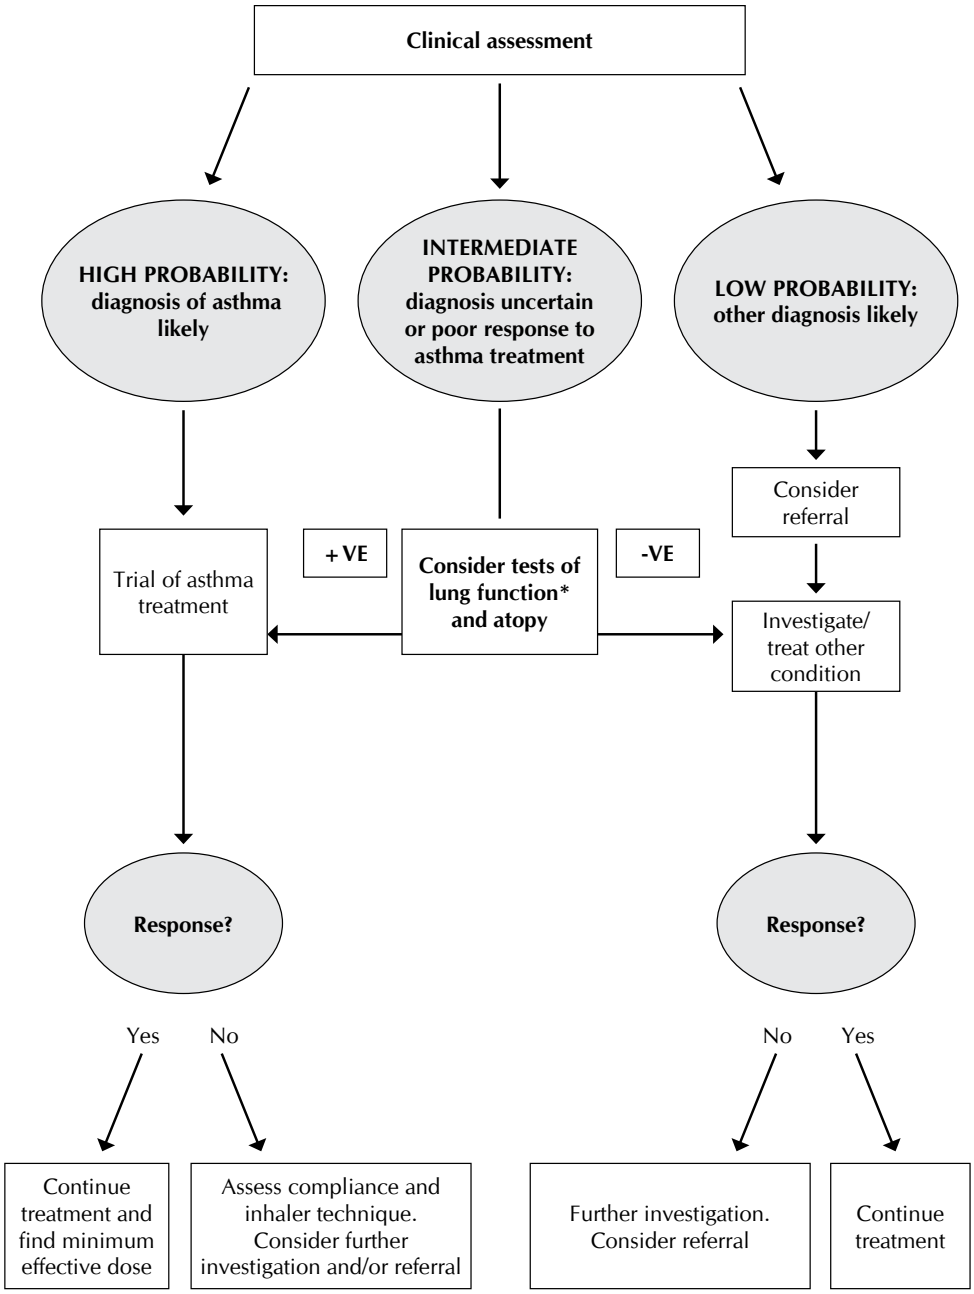
Using a structured questionnaire may produce a more standardised approach to the recording of presenting clinical features and the basis for a diagnosis of asthma.

1. **In children with a high probability of asthma:**
   - move straight to a trial of treatment
   - reserve further testing for those with a poor response.
2. **In children with a low probability of asthma:**
   - consider more detailed investigation and specialist referral.
3. **In children with an intermediate probability of asthma who can perform spirometry and have evidence of airways obstruction, offer a reversibility test and/or a trial of treatment for a specified period:**
   - if there is reversibility, or if treatment is beneficial, treat as asthma
   - if there is insignificant reversibility, and/or treatment trial is not beneficial, consider tests for alternative conditions.
4. **In children with an intermediate probability of asthma who can perform spirometry, and have no evidence of airways obstruction, consider testing for atopic status, bronchodilator reversibility and, if possible, bronchial hyper-responsiveness using methacholine or exercise.**
5. **In children with an intermediate probability of asthma, who cannot perform spirometry, consider testing for atopic status and offering a trial of treatment for a specified period:**
   - if treatment is beneficial, treat as asthma
   - if treatment is not beneficial, stop asthma treatment, and consider tests for alternative conditions and specialist referral.

Table 4: Indications for specialist referral in children

▪ Diagnosis unclear or in doubt
▪ Symptoms present from birth or perinatal lung problem
▪ Excessive vomiting or posseting
▪ Severe upper respiratory tract infection
▪ Persistent wet or productive cough
▪ Family history of unusual chest disease
▪ Failure to thrive
▪ Nasal polyps
▪ Unexpected clinical findings eg focal signs, abnormal voice or cry, dysphagia, inspiratory stridor
▪ Failure to respond to conventional treatment (particularly inhaled corticosteroids above 400 mcg/day or frequent use of steroid tablets)
▪ Parental anxiety or need for reassurance

Figure 1: Presentation with suspected asthma in children



* *Lung function tests include spirometry before and after bronchodilator (test of airway reversibility) and possible exercise or methacholine challenge (tests of airway responsiveness).*
Most children over the age of 5 years can perform lung function tests.

2.4 DIAGNOSIS IN ADULTS

The diagnosis of asthma is based on the recognition of a characteristic pattern of symptoms and signs and the absence of an alternative explanation for them *(see Table 5*). The key is to take a careful clinical history. In many cases this will allow a reasonably certain diagnosis of asthma, or an alternative diagnosis, to be made. If asthma does appear likely, the history should also explore possible causes, particularly occupational.

In view of the potential requirement for treatment over many years, it is important even in relatively clear cut cases, to try to obtain objective support for the diagnosis. Whether or not this should happen before starting treatment depends on the certainty of the initial diagnosis and the severity of presenting symptoms. Repeated assessment and measurement may be necessary before confirmatory evidence is acquired.

Confirmation hinges on demonstration of airflow obstruction varying over short periods of time. Spirometry, which is now becoming more widely available, is preferable to measurement of peak expiratory flow because it allows clearer identification of airflow obstruction, and the results are less dependent on effort. It should be the preferred test where available (although some training is required to obtain reliable recordings and to interpret the results). Of note, a normal spirogram (or PEF) obtained when the patient is not symptomatic does not exclude the diagnosis of asthma.

Results from spirometry are also useful where the initial history and examination leave genuine uncertainty about the diagnosis. In such cases, the differential diagnosis and approach to investigation is different in patients with and without airflow obstruction *(see Figure 2 and Table 6)*. In patients with a normal or near-normal spirogram when symptomatic, potential differential diagnoses are mainly non-pulmonary; [71,72] these conditions do not respond to inhaled corticosteroids and bronchodilators. In contrast, in patients with an obstructive spirogram the question is less whether they will need inhaled treatment but rather exactly what form and how intensive this should be.

Other tests of airflow obstruction, airway responsiveness and airway inflammation can also provide support for the diagnosis of asthma, but to what extent the results of the tests alter the probability of a diagnosis of asthma has not been clearly established, nor is it clear when these tests are best performed.

Table 5: Clinical features in adults that influence the probability that episodic respiratory symptoms are due to asthma

Features that increase the probability of asthma
▪ More than one of the following symptoms: wheeze, breathlessness, chest tightness and cough, particularly if: ◊ symptoms worse at night and in the early morning ◊ symptoms in response to exercise, allergen exposure and cold air ◊ symptoms after taking aspirin or beta blockers ▪ History of atopic disorder ▪ Family history of asthma and/or atopic disorder ▪ Widespread wheeze heard on auscultation of the chest ▪ Otherwise unexplained low FEV_1 or PEF (historical or serial readings) ▪ Otherwise unexplained peripheral blood eosinophilia
Features that lower the probability of asthma
▪ Prominent dizziness, light-headedness, peripheral tingling ▪ Chronic productive cough in the absence of wheeze or breathlessness ▪ Repeatedly normal physical examination of chest when symptomatic ▪ Voice disturbance ▪ Symptoms with colds only ▪ Significant smoking history (ie >20 pack-years) ▪ Cardiac disease ▪ Normal PEF or spirometry when symptomatic* * A normal spirogram/spirometry when not symptomatic does not exclude the diagnosis of asthma. Repeated measurements of lung function are often more informative than a single assessment.

☑ Base initial diagnosis on a careful assessment of symptoms and a measure of airflow obstruction:

- in patients with a high probability of asthma move straight to a trial of treatment. Reserve further testing for those whose response to a trial of treatment is poor.
- in patients with a low probability of asthma, whose symptoms are thought to be due to an alternative diagnosis, investigate and manage accordingly. Reconsider the diagnosis of asthma in those who do not respond.
- the preferred approach in patients with an intermediate probability of having asthma is to carry out further investigations, including an explicit trial of treatments for a specified period, before confirming a diagnosis and establishing maintenance treatment.

D **Spirometry is the preferred initial test to assess the presence and severity of airflow obstruction.**

2.4.1 FURTHER INVESTIGATION OF PATIENTS WITH AN INTERMEDIATE PROBABILITY OF ASTHMA

Patients with airways obstruction

Tests of peak expiratory flow variability, lung volumes, gas transfer, airway hyper-responsiveness and airway inflammation are of limited value in discriminating patients with established airflow obstruction due to asthma from those whose airflow obstruction is due to other conditions.[73-76] Patients may have more than one cause of airflow obstruction, which complicates the interpretation of any test. In particular, asthma and chronic obstructive pulmonary disease (COPD) commonly coexist.

☑ Offer patients with airways obstruction and intermediate probability of asthma a reversibility test and/or a trial of treatment for a specified period:

- if there is significant reversibility, or if a treatment trial is clearly beneficial treat as asthma
- if there is insignificant reversibility and a treatment trial is not beneficial, consider tests for alternative conditions.*

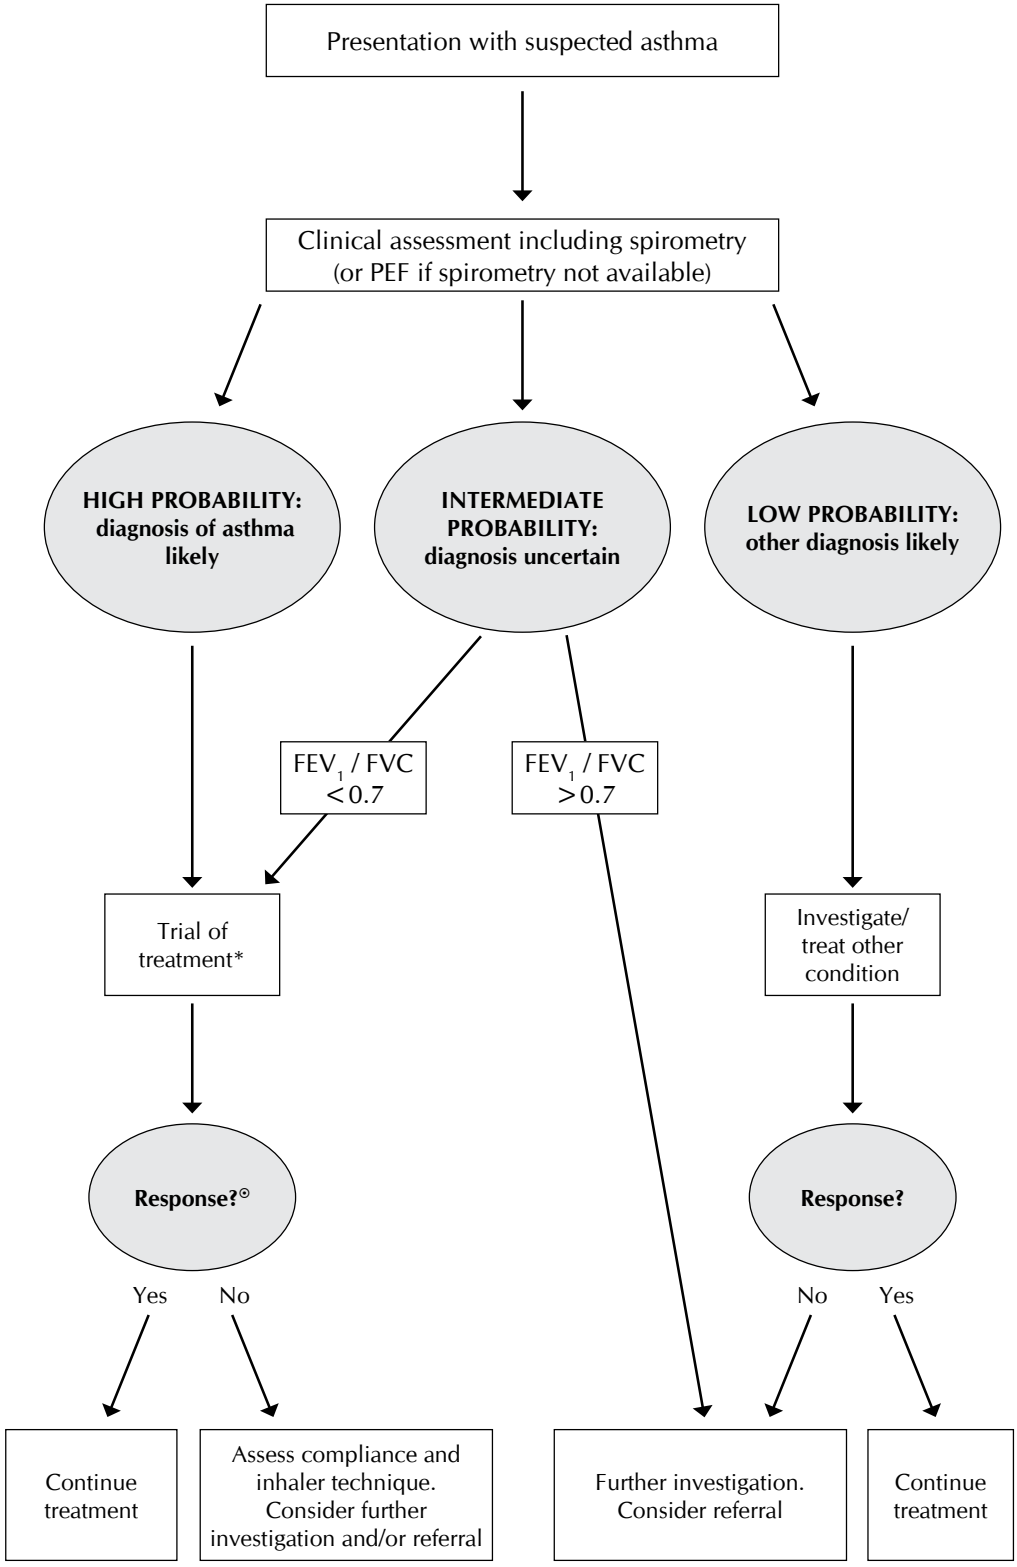
Patients without airways obstruction

In patients with a normal or near-normal spirogram it is more useful to look for evidence of airway hyper-responsiveness and/or airway inflammation [71,77-79] These tests are sensitive so normal results provide the strongest evidence against a diagnosis of asthma.

☑ In patients without evidence of airways obstruction and with an intermediate probability of asthma, arrange further investigations* before commencing treatment.

** see section 2.5 for more detailed information on further tests*

Figure 2: Presentation with suspected asthma in adults



*** See section 2.5.1**
⊙ See Table 6

Table 6: Differential diagnosis of asthma in adults, according to the presence or absence of airflow obstruction ($FEV_1/FVC < 0.7$).

Without airflow obstruction
▪ Chronic cough syndromes ▪ Hyperventilation syndrome ▪ Vocal cord dysfunction ▪ Rhinitis ▪ Gastro-oesophageal reflux ▪ Heart failure ▪ Pulmonary fibrosis
With airflow obstruction
▪ COPD ▪ Bronchiectasis* ▪ Inhaled foreign body* ▪ Obliterative bronchiolitis ▪ Large airway stenosis ▪ Lung cancer* ▪ Sarcoidosis* *may also be associated with non-obstructive spirometry

☑ Consider performing chest X-ray in any patient presenting atypically or with additional symptoms or signs. Additional investigations such as full lung function tests, blood eosinophil count, serum IgE and allergen skin prick tests may be of value in selected patients.

Criteria for referral to a specialist are outlined in box 1.

Box 1: Criteria for specialist referral in adults

- Diagnosis unclear
- Unexpected clinical findings (ie crackles, clubbing, cyanosis, cardiac disease)
- Unexplained restrictive spirometry
- Suspected occupational asthma
- Persistent non-variable breathlessness
- Monophonic wheeze or stridor
- Prominent systemic features (myalgia, fever, weight loss)
- Chronic sputum production
- CXR shadowing
- Marked blood eosinophilia ($>1 \times 10^9$/l)
- Poor response to asthma treatment
- Severe asthma exacerbation

2.5 FURTHER INVESTIGATIONS THAT MAY BE USEFUL IN PATIENTS WITH AN INTERMEDIATE PROBABILITY OF ASTHMA

Three studies have looked at tests to discriminate patients with asthma from those with conditions that are commonly confused with asthma.[71,77,79] These studies provide a basis for evaluating the diagnostic value of different tests. Table 7 summarises the sensitivity and specificity of different findings on investigation. As not all studies included patients with untreated asthma, these values may underestimate the value of the investigations in clinical practice, where many patients will be investigated before treatment is started. The diagnostic value of testing may also be greater when more than one test is done or if there are previous lung function results available in the patient's notes. The choice of test will depend on a number of factors including severity of symptoms and local availability of tests.

An alternative and promising approach to the classification of airways disease is to use tests which best identify patients who are going to respond to corticosteroid therapy.[78,80] A raised sputum eosinophil count and an increased exhaled nitric oxide concentration (FE_{NO}) are more closely related to corticosteroid response than other tests in a variety of clinical settings.[78,81-83] There is also evidence that markers of eosinophilic airway inflammation are of value in monitoring the response to corticosteroid treatment.[84-86] More experience with these techniques and more information on the long term response to corticosteroid in patients who do not have a raised sputum eosinophil count or FE_{NO} is needed before this approach can be recommended.

Table 7: Estimates of sensitivity and specificity of test results in adults with suspected asthma and normal or near-normal spirometric values.[71,77,79]

Test	Normal range	Validity	
		sensitivity	specificity
Methacholine PC_{20}	> 8 mg/ml	High	Medium
Indirect challenges*	varies	Medium#	High
FE_{NO}	< 25ppb	High#	Medium
Sputum eosinophil count	< 2%	High#	Medium
PEF A%H	< 8** < 20%***	Low	Medium

PC_{20} = the provocative concentration of methacholine required to cause a 20% fall in FEV_1. FE_{NO} = exhaled nitric oxide concentration. PEF A%H = peak expiratory flow amplitude percent highest.

**ie exercise challenge, inhaled mannitol # in untreated patients, **with twice daily readings ***with four or more readings*

2.5.1 TREATMENT TRIALS AND REVERSIBILITY TESTING

Treatment trials with bronchodilators or inhaled corticosteroids in patients with diagnostic uncertainty should use one or more objective methods of assessment. Using spirometric values or PEF as the prime outcome of interest is of limited value in patients with normal or near-normal pre-treatment lung function since there is little room for measurable improvement. One study has shown that the sensitivity of a positive response to inhaled corticosteroid, defined as a > 15% improvement in PEF, is 24%.[79] A variety of tools to assess asthma control is available to assess the response to a trial of treatment *(see Table 8).* | 2^+

Using FEV_1 or PEF as the primary method to assess reversibility or the response to treatment trials may be more helpful in patients with established airflow obstruction.

In adults, most clinicians would try a 6-8 week treatment trial of 200 mcg inhaled beclometasone (or equivalent) twice daily. In patients with significant airflow obstruction there may be a degree of inhaled corticosteroid resistance [87] and a treatment trial with oral prednisolone 30 mg daily for two weeks is preferred. | 2^+

A >400 ml improvement in FEV_1 to either β_2 agonists or corticosteroid treatment trials strongly suggests underlying asthma. Smaller improvements in FEV_1 are less discriminatory[71] and a decision on continuation of treatment should be based on objective assessment of symptoms using validated tools *(see Table 8)*. Trials of treatment withdrawal may be helpful where there is doubt. 2+

C **Assess FEV_1 (or PEF) and/or symptoms:**

- **before and after 400 mcg inhaled salbutamol in patients with diagnostic uncertainty and airflow obstruction present at the time of assessment**
- **in other patients, or if there is an incomplete response to inhaled salbutamol, after either inhaled corticosteroids** *(200 mcg twice daily beclometasone equivalent for 6-8 weeks)* **or oral prednisolone** *(30 mg once daily for 14 days).*

2.5.2 PEAK EXPIRATORY FLOW MONITORING

PEF should be recorded as the best of three forced expiratory blows from total lung capacity with a maximum pause of two seconds before blowing.[88] The patient can be standing or sitting. Further blows should be done if the largest two PEF are not within 40 l/min.[88]

PEF is best used to provide an estimate of variability of airflow from multiple measurements made over at least two weeks. Increased variability may be evident from twice daily readings. More frequent readings will result in a better estimate [89] but the improved precision is likely to be achieved at the expense of reduced patient compliance.[90]

PEF variability is best calculated as the difference between the highest and lowest PEF expressed as a percentage of either the mean or highest PEF.[91-93]

The upper limit of the normal range for the amplitude % highest is around 20% using four or more PEF readings per day [91,93,94] but may be lower using twice daily readings.[95] Epidemiological studies have shown sensitivities of between 19 and 33% for identifying physician-diagnosed asthma. [92,96]

PEF variability can be increased in patients with conditions commonly confused with asthma [71,73] so the specificity of abnormal PEF variability is likely to be less in clinical practice than it is in population studies.

PEF records from frequent readings taken at work and away from work are useful when considering a diagnosis of occupational asthma *(see section 7.8)*. A computer generated analysis of occupational records which provides an index of the work effect is available.[97]

☑ Peak flow records should be interpreted with caution and with regard to the clinical context. They are more useful in the monitoring of patients with established asthma than in making the initial diagnosis.

2.5.3 ASSESSMENT OF AIRWAY RESPONSIVENESS

Tests of airway responsiveness have been useful in research but are not yet widely available in everyday clinical practice. The most widely used method of measuring airway responsiveness relies on measuring response in terms of change in FEV_1 a set time after inhalation of increasing concentrations of histamine or methacholine. The agent can be delivered by breath-activated dosimeter, via a nebuliser using tidal breathing, or via a hand held atomiser.[98] The response is usually quantified as the concentration (or dose) required to cause a 20% fall in FEV_1 (PC_{20} or PD_{20}) calculated by linear interpolation of the log concentration or dose-response curve.

Community studies in adults have consistently shown that airway responsiveness has a unimodal distribution with between 90 and 95% of the normal population having a histamine or methacholine PC_{20} of >8 mg/ml (equivalent to a PD_{20} of >4 micromoles).[92,99,100] This value has a sensitivity of between 60-100% in detecting physician-diagnosed asthma.[92,96,99,100]

In patients with normal or near-normal spirometric values, assessment of airway responsiveness is significantly better than other tests in discriminating patients with asthma from patients with conditions commonly confused with asthma *(see Table 6)*.[71,77] In contrast, tests of airway responsiveness are of little value in patients with established airflow obstruction as the specificity is low.[73,76]

Other potentially helpful constrictor challenges include indirect challenges such as inhaled mannitol and exercise.[101] A positive response to these indirect stimuli (ie a >15% fall in FEV_1) is a specific indicator of asthma but the tests are less sensitive than tests using methacholine and histamine, particularly in patients tested while on treatment.[101,102]

2.5.4 TESTS OF EOSINOPHILIC AIRWAY INFLAMMATION

Eosinophilic airway inflammation can be assessed non-invasively using the induced sputum differential eosinophil count or the exhaled nitric oxide concentration (FE_{NO}).[103,104] A raised sputum eosinophil count (>2%) or FE_{NO} (>25 ppb at 50 ml/sec) is seen in 70-80% of patients with untreated asthma.[74,103] Neither finding is specific to asthma: 30-40% of patients with chronic cough [82,105,106] and a similar proportion of patients with COPD[81] have abnormal results. There is growing evidence that measures of eosinophilic airway inflammation are more closely linked to a positive response to corticosteroids than other measures even in patients with diagnoses other than asthma. [81,83,105]

Experience with induced sputum and FE_{NO} is limited to a few centres and more research needs to be done before any recommendations can be made.

C **In patients in whom there is diagnostic uncertainty and no evidence of airflow obstruction on initial assessment, test airway responsiveness wherever possible.**

2.6 MONITORING ASTHMA

In the majority of patients with asthma symptom-based monitoring is adequate. Patients achieving control of symptoms with treatment have a low risk for exacerbations.[107]

Table 8 summarises the methodology, measurement characteristics and interpretation of some of the validated tools used to assess symptoms and other aspects of asthma. Some measures provide information about future risk (ie sputum eosinophil count, airway responsiveness and FE_{NO}) rather than immediate clinical control. Risk reduction, eg minimising future adverse outcomes such as exacerbations and accelerated decline in lung function, is also a goal of asthma management.

A management strategy that controls eosinophilic airway inflammation [84-86] or airway hyper-responsiveness[108] results in better control of exacerbations than one which controls immediate clinical manifestations. The benefits of this more intensive approach are greater in patients with severe asthma, when exacerbations can occur frequently and unpredictably. More research is needed to assess the relative roles of the different measures and to address the feasibility and cost of incorporating them into monitoring protocols before they can be recommended more widely.

2.6.1 MONITORING IN PRIMARY CARE

Asthma is best monitored in primary care by routine clinical review on at least an annual basis *(see section 8.1.2)*.

The factors that should be monitored and recorded include:

- symptomatic asthma control: best assessed using directive questions such as the RCP '3 questions',[109] or the Asthma Control Questionnaire or Asthma Control Test *(see Table 8)*, since broad non-specific questions may underestimate symptoms
- lung function, assessed by spirometry or by PEF. Reduced lung function compared to previously recorded values may indicate current bronchoconstriction or a long term decline in lung function and should prompt detailed assessment
- exacerbations, oral corticosteroid use and time off work or school since last assessment
- inhaler technique *(see section 5)*
- compliance *(see section 9.2)* which can be assessed by reviewing prescription refill frequency
- bronchodilator reliance which can be assessed by reviewing prescription refill frequency
- possession of and use of self management plan/personal action plan *(see section 9.1)*.

Table 8: Summary of tools that can be used to assess asthma.

Measurement	Methodology	Measurement characteristics	Comments
Spirometry[110, 111]	Widely available. Enables clear demonstration of airflow obstruction. FEV_1 largely independent of effort and highly repeatable. Less applicable in acute severe asthma. Only assesses one aspect of the disease state.	Normal ranges widely available and robust. Short term (20 minute) 95% range for repeat measure of FEV_1 < 160 ml; FVC < 330 ml, independent of baseline value.	Good for short and longer term reversibility testing in subjects with pre-existing airflow obstruction. > 400 ml increase in FEV_1 highly suggestive of asthma. Less helpful in subjects with normal pre-treatment values because of ceiling effect.
Peak expiratory flow (PEF)[88, 91, 92, 112]	Widely available and simple. Applicable in a wide variety of circumstances including acute severe asthma. PEF variability can be determined from home readings in most subjects. PEF effort dependent and not as repeatable as FEV_1. Only assesses one aspect of the disease state.	Normal ranges of PEF are wide, and currently available normative tables are outdated and do not encompass ethnic diversity. Change in PEF more meaningful than absolute value. > 60 l/min increase in PEF suggested as best criteria for defining reversibility. Normal range of PEF variability defined as amplitude % highest < 8% or < 20% depending on number of readings and degree of patient coaching.	Useful for short and longer term reversibility testing in subjects with pre-existing airflow obstruction. Less helpful in subjects with normal pre-treatment values because of ceiling effect. Little information on the use of PEF variability as an index of treatment response.

Measurement	Methodology	Measurement characteristics	Comments
Royal College of Physicians (RCP) 3 Questions[109]	Yes/no or graded response to the following three questions: In the last week (or month) 1. Have you had difficulty sleeping because of your asthma symptoms (including cough)? 2. Have you had your usual asthma symptoms during the day (cough, wheeze, chest tightness or breathlessness)? 3. Has your asthma interfered with your usual activities (eg housework, work/ school etc)?	No to all questions consistent with controlled asthma.	Not well validated. Simplicity is attractive for use in day to day clinical practice.
Asthma Control Questionnaire[113-115]	Response to 7 questions, 5 relating to symptoms, 1 rescue treatment use and 1 FEV_1. Response usually assessed over the preceding week. Shortened, five question symptom only questionnaire is just as valid.	Well controlled ≤ 0.75, inadequately controlled ≥ 1.5. 95% range for repeat measure +/- 0.36. Minimal important difference 0.5.	Well validated composite scoring system with a strong bias to symptoms. Could be used to assess response to longer term treatment trials. Shortened five-point questionnaire is probably best for those with normal or near normal FEV_1.
Asthma Control Test (ACT)[116, 117]	Response to 5 questions, 3 related to symptoms, 1 medication use and 1 overall control. 5 point response score	Well controlled >19. Within subject intraclass correlation coefficient 0.77. 95% range for repeat measure and minimally clinically important difference not defined.	Could be used to assess response to longer term treatment trials, particularly in those with normal or near-normal spirometric values. 95% range for repeat measure and minimally clinically important difference need to be defined.

Measurement	Methodology	Measurement characteristics	Comments
Mini Asthma Quality of Life Questionnaire (AQLQ)[114, 118]	Response to 15 questions in 4 domains (symptoms, activity limitations, emotional function and environmental stimuli). Response usually assessed over the preceding week. Closely related to larger 32-item asthma quality of life questionnaire.	95% range for repeat measure +/- 0.36. Minimal important difference 0.5.	Well validated quality of life questionnaire. Could be used to assess response to longer term treatment trials.
Airway responsiveness[98, 108]	Only available in selected secondary care facilities. Responsive to change (particularly indirect challenges such as inhaled mannitol). Less of a ceiling effect. Not applicable in severe asthma or in acute severe asthma	Normal methacholine PC_{20} > 8 mg/ml. 95% range for repeat measure +/- 1.5-2 doubling doses.	Has not been widely used to monitor disease and assess treatment responses. Some evidence that using airway responsiveness as an additional measure for monitoring asthma results in a reduction in asthma exacerbations and improved airway pathology.

Measurement	Methodology	Measurement characteristics	Comments
Exhaled nitric oxide (FE_{NO})[78, 85, 103, 119, 120]	Not widely available. Monitors still expensive, although expect the technology to become cheaper and more widespread. Measurements can be obtained in almost all adults and children over 5 years. Immediate results are available. Reasonably close relationship between FE_{NO} and eosinophilic airway inflammation, which is independent of gender, age, atopy and inhaled corticosteroid use. Relationship is lost in smokers. Not closely related to other measures of asthma morbidity.	Normal range < 25 ppb at exhaled flow of 50 ml/sec. 95% range for repeat measure 4 ppb. > 50 ppb highly predictive of eosinophilic airway inflammation. < 25 ppb highly predictive of its absence.	Raised FE_{NO} (> 50 ppb) very predictive of a positive response to corticosteroids. Use of FE_{NO} to guide corticosteroid treatment has been shown to result in a non-significant 25% reduction in exacerbations with 40% less corticosteroid. Low FE_{NO} (< 25 ppb) may be of particular value in identifying patients who can step down corticosteroid treatment safely. Protocols for diagnosis and monitoring have not been well defined and experience with the technique is limited.
Sputum eosinophil differential count[83, 84, 121, 122]	Only available in specialist centres although technology is widely available and inexpensive. Information available in 80-90% of patients although immediate results are not available. Sputum eosinophil count not closely related to other measures of asthma morbidity	Normal range < 2%; 95% range for repeat measure +/- 2-3 fold.	Close relationship between raised sputum eosinophil count and corticosteroid responsiveness. Use of sputum eosinophil count to guide corticosteroid therapy has been consistently shown to result in better outcome for the same exposure to corticosteroids. Benefits are greater in patients with more severe disease.

3 Non-pharmacological management

There is a common perception amongst patients and carers that there are numerous environmental, dietary and other triggers of asthma and that avoiding these triggers will improve asthma and reduce the requirement for pharmacotherapy. Failure to address a patient, parent or carer's concern about environmental triggers may compromise concordance with recommended pharmacotherapy. Evidence that non-pharmacological management is effective can be difficult to obtain and more well controlled intervention studies are required.

This section distinguishes:

1. primary prophylaxis - interventions introduced before the onset of disease and designed to reduce its incidence.
2. secondary prophylaxis - interventions introduced after the onset of disease to reduce its impact.

3.1 PRIMARY PROPHYLAXIS

The evidence for primary interventional strategies is based predominantly on observational studies, though some have been tested using experimental methods. Many are multifaceted and it can be difficult to disentangle the effects of one exposure or intervention from another.

3.1.1 AEROALLERGEN AVOIDANCE

Exposure to high levels of house dust mite allergen in early life is associated with an increased likelihood of sensitisation to house dust mite by three to seven years of age.[123] Sensitisation to house dust mite is an important risk factor for the development of asthma[124,125] and a few studies have suggested that high early house dust mite exposure increases the risks of subsequent asthma.[126,127] A UK study showed that low levels of house dust mite and cat allergen exposures in early life increased the risk of IgE sensitisation and asthma at five years, with some attenuation at high levels of exposure, but there were significant interactions with heredity and birth order.[128]

Outcomes from intervention studies attempting to reduce exposure to house dust mites are inconsistent. A multifaceted Canadian intervention study showed a reduced prevalence of doctor-diagnosed asthma but no impact on other allergic diseases, positive skin prick tests or bronchial hyper-responsiveness;[129] others have shown no effect on either allergic sensitisation or symptoms of allergic diseases.[130] In one UK study, early results from environmental manipulation commenced in early pregnancy and focused mainly on house dust mite avoidance, showed reductions in some respiratory symptoms in the first year of life.[131] Subsequent results showed a paradoxical effect with increased allergy but better lung function in the intervention group.[132] 1+

The considerable variation in the methodology used in these studies precludes the merging of data or generation of meta-analyses.

Intensive house dust mite avoidance may reduce exposure to a range of other factors including endotoxin. Epidemiological studies suggest that close contact with a cat or a dog in early life may reduce the subsequent prevalence of allergy and asthma.[133,134] This has raised the question of whether high pet allergen exposure causes high-dose immune tolerance or increases exposure to endotoxin and other microbial products as a component of the "hygiene hypothesis".

In the absence of consistent evidence of benefit from domestic aeroallergen avoidance it is not possible to recommend it as a strategy for preventing childhood asthma.

3.1.2 FOOD ALLERGEN AVOIDANCE

Sensitisation to foods, particularly eggs, frequently precedes the development of aeroallergy and subsequent asthma.[135] Food allergen avoidance in pregnancy and postnatally has not been shown to prevent the later development of asthma.[136] Allergen avoidance during pregnancy may adversely affect maternal, and perhaps fetal, nutrition.[137] High-dose food allergen exposure during pregnancy may reduce subsequent sensitisation rates by inducing tolerance.[138] 1+

B **In the absence of any evidence of benefit and given the potential for adverse effects, maternal food allergen avoidance during pregnancy and lactation is not recommended as a strategy for preventing childhood asthma.**

3.1.3 BREAST FEEDING

A systematic review of observational studies on the allergy preventive effects of breast feeding indicates that it is effective for all infants irrespective of allergic heredity. The preventive effect is more pronounced in high-risk infants provided they are breast fed for at least four months.[139] However, not all studies have demonstrated benefit and in a large birth cohort there was no protective effect against atopy and asthma and maybe even an increase in risk.[140] 2+

Observational studies have the potential to be confounded by, for example, higher rates of breast feeding in atopic families, and taking this into account, the weight of evidence is in favour of breast feeding as a preventive strategy.

C **Breast feeding should be encouraged for its many benefits, and as it may also have a potential protective effect in relation to early asthma.**

3.1.4 MODIFIED INFANT MILK FORMULAE

Trials of modified milk formulae have not included sufficiently long follow up to establish whether there is any impact on asthma. A Cochrane review identified inconsistencies in findings and methodological concerns amongst studies, which mean that hydrolysed formulae cannot currently be recommended as part of an asthma prevention strategy.[141] A review of the use of soy formulae found no significant effect on asthma or any other allergic disease.[142] 1+

In the absence of any evidence of benefit from the use of modified infant milk formulae it is not possible to recommend it as a strategy for preventing childhood asthma.

3.1.5 WEANING

There are conflicting data on the association between early introduction of allergenic foods into the infant diet and the subsequent development of allergy and atopic eczema. No evidence was identified in relation to asthma.[143] In one study late introduction of egg was associated with a non-significant increase in pre-school wheezing.[144]

In the absence of evidence on outcomes in relation to asthma no recommendations on modified weaning can be made.

3.1.6 NUTRITIONAL SUPPLEMENTATION - FISH OILS

Fish oils have a high level of omega-3 polyunsaturated fatty acids (n-3PUFAs). Western diets have a low intake of n-3 PUFAs with a corresponding increase in intake of n-6 PUFAs. This change has been associated with increasing rates of allergic disease and asthma.[143] Two randomised controlled studies have investigated early life fish oil dietary supplementation in relation to asthma outcomes in children at high risk of atopic disease (at least one parent or sibling had atopy with or without asthma). In a study, powered only to detect differences in cord blood, maternal dietary fish oil supplementation during pregnancy was associated with reduced cytokine release from allergen stimulated cord blood mononuclear cells. However, effects on clinical outcomes at one year, in relation to atopic eczema, wheeze and cough, were marginal.[145] In a second study, fish oil supplementation commencing in early infancy with or without additional house dust mite avoidance, was associated with a significant reduction in wheeze at 18 months of age. By five years of age fish oil supplementation was not associated with effects on asthma or other atopic diseases.[146] 1+

In the absence of any evidence of benefit from the use of fish oil supplementation in pregnancy it is not possible to recommend it as a strategy for preventing childhood asthma.

3.1.7 OTHER NUTRIENTS

A number of observational studies have suggested an increased risk of subsequent asthma following reduced (maternal) intakes of selenium (based on umbilical cord levels),[147]or vitamin E based on maternal pregnancy intake.[148] No intervention studies in relation to selenium or vitamin E have yet been conducted and overall there is insufficient evidence to make any recommendations on maternal dietary supplementation as an asthma prevention strategy.[143] Observational studies suggest that intervention trials are warranted.

3.1.8 MICROBIAL EXPOSURE

The "hygiene hypothesis" suggested that early exposure to microbial products would switch off allergic responses thereby preventing allergic diseases such as asthma. The hypothesis is supported by some epidemiological studies comparing large populations who have or have not had such exposure.[149,150]

The concept is sometimes described as "the microbial exposure hypothesis". A double blind placebo controlled trial of the probiotic lactobacillus GG given to mothers resulted in a reduced incidence of atopic eczema in their children but had no effect on IgE antibody or allergic skin test responses. The small sample size and short follow up in this study limit its interpretation.[151] Other trials of a range of probiotics and prebiotics are now in progress. There remains insufficient understanding of the ecology of gut flora in infancy in relation to outcomes. Bifido-bacteria may be more important than lactobacilli in reducing susceptibility to allergic disease.[152]

There is insufficient evidence to indicate that the use of dietary probiotics in pregnancy reduces the incidence of childhood asthma.

This is a key area for further work with longer follow up to establish outcomes in relation to asthma.

3.1.9 AVOIDANCE OF TOBACCO SMOKE AND OTHER AIR POLLUTANTS

No evidence has been found to support a link between exposure to environmental tobacco smoke (ETS) or other air pollutants and the induction of allergy.

There is an increased risk of infant wheezing associated with maternal smoking during pregnancy which adversely affects infant lung function.[153-156] Evidence suggests that early life ETS exposure is associated with later persistent asthma[157,158] with a strong interaction with genetic polymorphisms which affect antioxidant activity.[159] 2+

B **Parents and parents-to-be should be advised of the many adverse effects which smoking has on their children including increased wheezing in infancy and increased risk of persistent asthma.**

The limited data on antenatal or early life exposure to other pollutants suggest similar effects to those for ETS, namely increased infant wheezing, enhanced by additional ETS exposure and antioxidant gene variations.[160-162] There is one small study suggesting that vitamin C supplementation will modify the combined effects of genetic polymorphisms and pollution on lung function in children with asthma.[163] Further research is required before recommendations for practice can be made. 3 4

3.1.10 IMMUNOTHERAPY

Three observational studies with contemporaneous untreated controls in over 8,000 patients have shown that allergen immunotherapy in individuals with a single allergy reduces the numbers subsequently developing new allergic sensitisation over a three to four year follow up.[164-166] One trial compared pollen allergen immunotherapy in children with allergic rhinitis with contemporaneous untreated controls and showed a lower rate of onset of asthma during three years of treatment.[167] This effect was sustained for two years after stopping the therapy.[168] More studies are required to establish whether immunotherapy might have a role in primary prophylaxis.

3.1.11 IMMUNISATION

In keeping with the "microbial exposure hypothesis" some studies have suggested an association between tuberculin responsiveness and subsequent reduced prevalence of allergy, implying a protective effect of BCG. At present, it is not possible to disentangle whether poor tuberculin responsiveness represents an underlying defect which increases the risk of allergy and asthma or whether the immunisation itself has a protective effect.[169] 2^+

Investigation of the effects of any other childhood immunisation suggests that at worst there is no influence on subsequent allergic disease and maybe some protective effect against the development of asthma.[170]

C **All childhood immunisations should proceed normally as there is no evidence of an adverse effect on the incidence of asthma.**

3.2 SECONDARY NON-PHARMACOLOGICAL PROPHYLAXIS

3.2.1 HOUSE DUST MITE AVOIDANCE

Increased allergen exposure in sensitised individuals is associated with an increase in asthma symptoms, bronchial hyper-responsiveness and deterioration in lung function.[127,171,172] However, evidence that reducing allergen exposure can reduce morbidity and/or mortality in asthma is tenuous. In uncontrolled studies, children and adults have derived benefit from removal to a low allergen environment such as occurs at high altitude, although the benefits seen are not necessarily attributable to allergen avoidance alone.[173]

Cochrane reviews on house dust mite control measures in a normal domestic environment have concluded that chemical and physical methods aimed at reducing exposure to house dust mite allergens cannot be recommended.[174] Subsequent studies involving large numbers of patients tend to support this conclusion.[175,176] Heterogeneity between studies with regard to the intervention and monitoring of outcomes makes interpretation of the systematic review difficult. 1^{++}

Studies of mattress barrier systems have suggested that benefits in relation to treatment requirements for asthma and lung function can occur.[177,178] Larger and more carefully conducted controlled studies employing combinations of house dust mite reduction strategies are required. At present house dust mite control measures do not appear to be a cost-effective method of achieving benefit, although it is recognised that many families are very committed to attempts to reduce exposure to triggers. 2^+

Measures to decrease house dust mites have been shown to reduce numbers of house dust mites, but have not been shown to have an effect on asthma severity.

☑ Families with evidence of house dust mite allergy and who wish to try mite avoidance might consider the following:

- complete barrier bed-covering systems
- removal of carpets
- removal of soft toys from bed
- high temperature washing of bed linen
- acaricides to soft furnishings
- good ventilation with or without dehumidification.

3.2.2 OTHER ALLERGENS

Animal allergens, particularly from cat and dog, are potent provokers of asthma symptoms. The reported effects of removal of pets from homes are paradoxical, with either no benefit for asthma[179,180] or a potential for continued high exposure to induce a degree of tolerance.[181] In homes where there is no cat but still detectable cat allergen, there may be a benefit from introducing additional avoidance measures such as air filters and high efficiency vacuum cleaners for cat allergic patients.[182,183]

Although fungal exposure has been strongly associated with hospitalisation and increased mortality in asthma, no controlled trials have addressed the efficacy of reduction of fungal exposure in relation to control of asthma. Cockroach allergy is not a common problem in the UK and studies of attempts to avoid this allergen elsewhere have produced conflicting results.[184]

Studies of individual aeroallergen avoidance strategies show that single interventions have limited or no benefit. A multi faceted approach is more likely to be effective if it addresses all the indoor asthma triggers. Such approaches may even be cost effective.[185] A strategy with a potential impact on mites, mould allergens and indoor pollutants is the use of a mechanical ventilation system to reduce humidity and increase indoor air exchange. The only trial that has assessed this in a controlled fashion failed to demonstrate any significant effects, but the numbers involved were small.[120] A systematic review of this topic concluded that more research is required.[186]

3.3 OTHER ENVIRONMENTAL FACTORS

3.3.1 SMOKING

Direct or passive exposure to cigarette smoke adversely affects quality of life, lung function, need for rescue medications for acute episodes of asthma and long term control with inhaled steroids.[187-190]

There are very few trials which have assessed smoking cessation in relation to asthma control. Two studies have demonstrated decreases in childhood asthma severity when parents were able to stop smoking.[191,192] One study in adults with asthma suggested that smoking cessation improved asthma-specific quality of life, symptoms and drug requirements.[193] Intervention to reduce smoking has had disappointing outcomes.[194,195] It is likely that more intensive intervention will be required to achieve meaningful outcomes.[196] 2+

Uptake of smoking in teenagers increases the risks of persisting asthma. One study showed a doubling of risk for the development of asthma over six years in 14 year old children who started to smoke[197] *(see section 4.2.4 for effect of smoking on treatment).* 3

C **Parents with asthma should be advised about the dangers of smoking to themselves and their children with asthma and offered appropriate support to stop smoking.**

3.3.2 AIR POLLUTION

Challenge studies demonstrate that various pollutants can enhance the response of patients with asthma to allergen inhalation.[198,199] Time-series studies suggest that air pollution may provoke acute asthma attacks or aggravate existing chronic asthma although the effects are very much less than those with infection or allergen exposure.[200,201] While it might seem likely that moving from a highly polluted environment might help, in the UK, asthma is more prevalent in 12-14 year olds in non-metropolitan rather than metropolitan areas.[202] Much less attention has been focused on indoor pollutants in relation to asthma and more work is required.[203,204]

3.3.3 IMMUNOTHERAPY

Subcutaneous immunotherapy

Trials of allergen specific immunotherapy by subcutaneous injection of increasing doses of allergen extracts have consistently demonstrated beneficial effects compared with placebo in the management of allergic asthma. Allergens included house dust mite, grass pollen, tree pollen, cat and dog allergen and moulds. Cochrane reviews have concluded that immunotherapy reduces asthma symptoms, the use of asthma medications and improves bronchial hyper-reactivity. The most recent review included 36 trials with house dust mite, 20 with pollen, 10 with animal allergens, two with cladosporium mould, one with latex and six with multiple allergens.[205] 1++

Evidence comparing the roles of immunotherapy and pharmacotherapy in the management of asthma is lacking. One study directly compared allergen immunotherapy with inhaled steroids and found that symptoms and lung function improved more rapidly in the group on inhaled steroids.[206] Further comparative studies are required. 2+

Immunotherapy for allergic rhinitis has been shown to have a carry over effect after therapy has stopped.[207] 3

B **Immunotherapy can be considered in patients with asthma where a clinically significant allergen cannot be avoided. The potential for severe allergic reactions to the therapy must be fully discussed with patients.**

Sublingual immunotherapy

There has been increasing interest in the use of sublingual immunotherapy, which is associated with far fewer adverse reactions than subcutaneous immunotherapy. A systematic review suggested there were some benefits for asthma control but the magnitude of the effect was small.[208] Further randomised controlled trials are required. 1++

B **Sublingual immunotherapy cannot currently be recommended for the treatment of asthma in routine practice.**

3.4 DIETARY MANIPULATION

3.4.1 ELECTROLYTES

Increasing dietary sodium has been implicated in the geographical variations in asthma mortality[209] and high sodium intake is associated with increased bronchial hyper-responsiveness.[210,211] A systematic review of intervention studies reducing salt intake identified only minimal effects and concluded that dietary salt reduction could not be recommended in the management of asthma.[212] Low magnesium intakes have been associated with a higher prevalence of asthma with increasing intake resulting in reduced bronchial hyper-responsiveness and higher lung function.[213] Magnesium plays a beneficial role in the treatment of asthma through bronchial smooth muscle relaxation, leading to the use of intravenous or inhaled preparations of magnesium sulphate for acute exacerbations of asthma.[214] Studies of oral supplementation are limited and more trials are required.[215-217]

3.4.2 FISH OILS/LIPIDS

In vitro studies suggest that supplementing the diet with omega n-3 fatty acids, which are most commonly found in fish oils, might reduce the inflammation associated with asthma.[218,219] Results from observational studies are inconsistent and a Cochrane review of nine randomised controlled trials concluded that there was insufficient evidence to recommend fish oil supplementation for the treatment of asthma.[220]

3.4.3 ANTIOXIDANTS

Observational studies have reported that low vitamin C, vitamin E and selenium intakes are associated with a higher prevalence of asthma.[143] Intervention studies suggest that neither supplementation with vitamin C, vitamin E or selenium is associated with clinical benefits in people with asthma.[221-223] Observational studies in both adults and children have also consistently shown that a high intake of fresh fruit and vegetable is associated with less asthma and better pulmonary function.[224-230] No intervention studies evaluating the intake of fruit or vegetables and their effects on asthma have been reported.

3.4.4 WEIGHT REDUCTION IN OBESE PATIENTS WITH ASTHMA

Several studies have reported an association between increasing body mass index and symptoms of asthma.[231-234] One randomised parallel group study has shown improved asthma control following weight reduction in obese patients with asthma.[235] 3 1+

C **Weight reduction is recommended in obese patients with asthma to promote general health and to improve asthma control.**

3.4.5 PROBIOTICS

Studies have suggested that an imbalance in gut flora is associated with a higher risk of development of allergy.[236] Trials have investigated the use of probiotics in the treatment of established allergic disease with variable results.[237,238] Only one study focused on asthma, finding a decrease in eosinophilia but no effect on clinical parameters.[239] 1+ 2+

In the absence of evidence of benefit, it is not possible to recommend the use of probiotics in the management of asthma.

3.4.6 IMMUNISATIONS

A number of large studies have concluded that high vaccination coverage has no significant impact on any allergic outcome or asthma. There is a suggestion that the higher the vaccine coverage the greater the possibility that there is a degree of protection against the development of allergy in the first years of life.[240-243]

There is some discussion about whether BCG immunisation may confer protection against allergy and asthma. Research has focused on primary prophylaxis, though there are some studies investigating the use of BCG, with or without allergen, as a means to switch off allergic immune responses. There are some observations suggesting that benefit might occur, [244] but results of trials have been disappointing.[245,246] This is an area that requires further investigation.

There has been concern that influenza vaccination might aggravate respiratory symptoms, though any such effect would be outweighed by the benefits of the vaccination.[247] Studies in children have suggested that immunisation with the vaccine does not exacerbate asthma[248] but has a small beneficial effect on quality of life in children with asthma.[249] The immune response to the immunisation may be adversely affected by high-dose inhaled corticosteroid therapy and this requires further investigation.[250] A Cochrane review of pneumococcal vaccine found very limited evidence to support its use specifically in individuals with asthma.[251] 1++

B **Immunisations should be administered independent of any considerations related to asthma. Responses to vaccines may be attenuated by high-dose inhaled steroids.**

3.5 COMPLEMENTARY AND ALTERNATIVE MEDICINE

Successive reviews have concluded that the evidence to support any recommendations on complementary or alternative medicine is lacking.[252] It is recognised that a lack of evidence does not necessarily mean that treatment is ineffective and high quality research, conducted in the same rigorous and objective fashion as that for conventional therapy, is required.

3.5.1 ACUPUNCTURE

A Cochrane review of 21 trials highlighted many methodological problems with the studies reviewed. Only seven of the trials in 174 patients employed randomisation to active (recognised in traditional Chinese medicine to be of benefit in asthma) or sham acupuncture points (with no recognised activity) for the treatment of persistent or chronic asthma. Blinding was a major problem in the assessment of the results and there were considerable inconsistencies in methodology. The review concluded that there was no evidence for a clinically valuable benefit for acupuncture and no significant benefits in relation to lung function.[253] A later systematic review and meta-analysis of 11 randomised controlled trials found no evidence of an effect in reducing asthma severity but a suggestion that where broncho-constriction was induced to establish efficacy of acupuncture there was a beneficial effect. Concern was expressed about potential preferential publication in favour of positive outcome studies.[254] Two other trials of acupuncture in relation to induced asthma were also negative.[255,256] 1+

3.5.2 AIR IONISERS

Ionisers have been widely promoted as being of benefit for patients with asthma. A Cochrane review of five studies using negative ion generators and one with a positive ion generator found no evidence of benefit in reducing symptoms in patients with asthma.[257] One study demonstrated an increase in night-time cough to a level which approached statistical significance.[258] 1++ 1+

A **Air ionisers are not recommended for the treatment of asthma.**

3.5.3 BREATHING EXERCISES INCLUDING YOGA AND THE BUTEYKO BREATHING TECHNIQUE

The principle of yoga and Buteyko breathing technique is to control hyperventilation by lowering respiratory frequency. A Cochrane review of breathing exercises found no change in routine measures of lung function.[259] One study showed a small reduction in airway responsiveness to histamine utilising pranayama, a form of yoga breathing exercise.[260] 1++ 1+

The Buteyko breathing technique specifically focuses on control of hyperventilation and any ensuing hypocapnia. Four clinical trials suggest benefits in terms of reduced symptoms and bronchodilator usage but no effect on lung function.[261-264] 1+

B **Buteyko breathing technique may be considered to help patients to control the symptoms of asthma.**

3.5.4 HERBAL AND TRADITIONAL CHINESE MEDICINE

A Cochrane review identified 17 trials, nine of which reported some improvement in lung function but it was not clear that the results would be generalisable.[265] A more recent double blind placebo controlled trial of a Chinese herb decoction (Ding Chuan Tang) showed improvement in airway hyper-responsiveness in children with stable asthma.[266] It is difficult to disentangle the effects of multiple ingredients; Ding Chuan Tang for example contains nine components. In a second study,100 children with asthma found that a five-herb mixture gave some benefits in relation to lung function and symptoms compared with placebo.[267] 1+

The conclusions of these trials of Chinese herbal therapy are not generalisable due to variations in the herbal mixtures and study designs. There are likely to be pharmacologically active ingredients in the mixtures and further investigations are warranted. There is a need for large appropriately powered placebo controlled studies.

3.5.5 HOMEOPATHY

A Cochrane review identified only three methodologically sound randomised controlled trials, two of which reported some positive effects. A criticism of the studies was that they did not employ individualised homeopathy, which is the essence of this approach to treatment.[268] A more recent trial of individualised homeopathy in childhood asthma, which was placebo controlled and appropriately powered, failed to show any evidence of benefit over conventional treatment in primary care.[269]

1++
1+

3.5.6 HYPNOSIS AND RELAXATION THERAPIES

A systematic review of relaxation therapies, including hypnotherapy, identified five controlled trials, two of which showed some benefits. Overall the methodology of the studies was poor and the review concluded that there was a lack of evidence of efficacy but that muscle relaxation could conceivably benefit lung function in patients with asthma.[270]

1++

3.6 OTHER COMPLEMENTARY OR ALTERNATIVE APPROACHES

3.6.1 MANUAL THERAPY INCLUDING MASSAGE AND SPINAL MANIPULATION

A Cochrane review identified four relevant RCTs.[271] The two trials of chiropractic suggest that there is no place for this modality of treatment in the management of asthma. No conclusions can be drawn on massage therapy.

3.6.2 PHYSICAL EXERCISE TRAINING

A Cochrane review [259] has shown no effect of physical training on PEF, FEV_1, FVC or VEmax. However, oxygen consumption, maximum heart rate, and work capacity all increased significantly. Most studies discussed the potential problems of exercise induced asthma, but none made any observations on this phenomenon. As physical training improves indices of cardiopulmonary efficiency, it should be seen as part of a general approach to improving lifestyle and rehabilitation in asthma, with appropriate precautions advised about exercise induced asthma *(see section 4.7.2)*.

3.6.3 FAMILY THERAPY

A Cochrane review identified two trials, in 55 children, showing that family therapy may be a useful adjunct to medication in children with asthma.[272] Small study size limits the recommendations.

☑ In difficult childhood asthma, there may be a role for family therapy as an adjunct to pharmacotherapy.

Revised 2009

4 Pharmacological management

The aim of asthma management is control of the disease. Control of asthma is defined as:

- no daytime symptoms
- no night-time awakening due to asthma
- no need for rescue medication
- no exacerbations
- no limitations on activity including exercise
- normal lung function (in practical terms FEV_1 and/or PEF > 80% predicted or best) with minimal side effects.

In clinical practice patients may have different goals and may wish to balance the aims of asthma management against the potential side effects or inconvenience of taking medication necessary to achieve perfect control.

☑ Lung function measurements cannot be reliably used to guide asthma management in children under five years of age.

A stepwise approach aims to abolish symptoms as soon as possible and to optimise peak flow by starting treatment at the level most likely to achieve this. Patients should start treatment at the step most appropriate to the initial severity of their asthma. The aim is to achieve early control and to maintain by stepping up treatment as necessary and stepping down when control is good *(see figures 4, 5 and 6 for summaries of stepwise management in adults and children)*.

☑ Before initiating a new drug therapy practitioners should check compliance with existing therapies *(see section 9.2)*, inhaler technique *(see section 5)* and eliminate trigger factors *(see section 3)*.

2009 Until May 2009 all doses of inhaled steroids in this section have been referenced against beclometasone (BDP) given via CFC-MDIs (metered dose inhaler). As BDP CFC is phased out, the reference inhaled steroid will be the BDP-HFA equivalent, which can be used at the same dosage. Adjustments to doses will have to be made for other devices and other corticosteroid molecules *(see section 4.2)*.

In this and the following section, each recommendation has been graded and the supporting evidence assessed for adults (>12 years old), children 5-12 years, and children under 5 years. The evidence is less clear in children under two and the threshold for seeking an expert opinion should be lowest in these children.

1 2 3 **1 Adults**
2 Children aged 5-12 years
3 Children under 5 years

■ **Recommendation does not apply to this age group.**

4.1 STEP 1: MILD INTERMITTENT ASTHMA

>12 years	5-12 years	<5 years
1++	1+	4
1+	1++	
1++		
1++		

The following medicines act as short-acting bronchodilators:

inhaled short-acting β_2 agonists[273]

inhaled ipratropium bromide[274]

β_2 agonist tablets or syrup[273]

theophyllines.[273]

Short-acting inhaled β_2 agonists work more quickly and/or with fewer side effects than the alternatives.[273]

A B C **Prescribe an inhaled short-acting β_2 agonist as short term reliever therapy for all patients with symptomatic asthma.**

4.1.1 FREQUENCY OF DOSING OF INHALED SHORT-ACTING β_2 AGONISTS

>12 years	5-12 years	<5 years
1++	1++	1++

Using short-acting β_2 agonists as required is at least as good as regular (four times daily) administration.[275,276] Unless individual patients are shown to benefit from regular use of inhaled short-acting β_2 agonists then as required use is recommended.

Good asthma control is associated with little or no need for short-acting β_2 agonist. Using two or more canisters of β_2 agonists per month or >10-12 puffs per day is a marker of poorly controlled asthma that puts patients at risk of fatal or near-fatal asthma.

☑ Patients with a high usage of inhaled short-acting β_2 agonists should have their asthma management reviewed.

4.2 STEP 2: INTRODUCTION OF REGULAR PREVENTER THERAPY

For steps 2, 3, and 4, treatments have been judged on their ability to improve symptoms, improve lung function, and prevent exacerbations, with an acceptable safety profile. Improvement of quality of life, while important, is the subject of too few studies to be used to make recommendations at present.

4.2.1 COMPARISON OF INHALED STEROIDS

Many studies comparing different inhaled steroids are of inadequate design and have been omitted from further assessment. In view of the clear differences between normal volunteers and asthma patients in the absorption of inhaled steroids, data from normal volunteers have not been taken into account. Only studies in which more than one dose of at least one of the inhaled steroids or both safety and efficacy had been studied together in the same trial were evaluated. Non-blinded studies also had to be considered because of the problems of obtaining competitors' delivery devices. A series of Cochrane reviews comparing different inhaled steroids using a different methodology have come to the same conclusion.

BDP and budesonide are approximately equivalent in clinical practice, although there may be variations with different delivery devices. There is limited evidence from two open studies of less than ideal design that budesonide via the turbohaler is more clinically effective.[295] However, at present a 1:1 ratio should be assumed when changing between BDP and budesonide.

Fluticasone provides equal clinical activity to BDP and budesonide at half the dosage. The evidence that it causes fewer side effects at doses with equal clinical effect is limited.

Mometasone appears to provide equal clinical activity to BDP and budesonide at half the dosage.[296] The relative safety of mometasone is not fully established.

2009

Table 8b: Equivalent doses of inhaled steroids relative to BDP and current licensed age indications

These dosage equivalents are approximate and will depend on other factors such as inhaler technique.

		UK licence covers		
Steroid	**Equivalent dose**	**>12 years**	**5 – 12 years**	**<5 years**
Beclometasone dipropionate CFC	400 mcg	**No longer available**		
Beclometasone				
Clenil modulite	400 mcg	✓	✓	✓
Clickhaler		✓	Over age 6	×
Aerobec Autohaler		✓	×	×
Asmabec Clickhaler		✓	Over age 6	×
Dry powder (Becodisks)		✓	✓	✓
Easyhaler		✓	×	×
Pulvinal		✓	Over age 6	×
Filair		✓	✓	✓
Qvar	200 to 300 mcg	✓	×	×
Fostair	200 mcg	Over age 18	×	×
Budesonide				
Turbohaler	400 mcg	✓	✓	×
Metered dose inhaler		✓	✓	Over age 2
Easyhaler		✓	Over age 6	×
Novolizer		✓	Over age 6	×
Symbicort		✓	Over age 6	×
Symbicort (regular and as required dosing)		Over age 18	×	×
Fluticasone				
Metered dose inhaler (HFA)	200 mcg	✓	✓	Over age 4
Accuhaler		✓	✓	Over age 4
Seretide HFA		✓	✓	Over age 4
Seretide (Accuhaler)		✓	✓	Over age 4
Mometasone	200 mcg	✓	×	×
Ciclesonide	200 to 300 mcg	✓	×	×

Ciclesonide is a new inhaled steroid. Evidence from clinical trials suggests that it has less systemic activity and fewer local oropharyngeal side effects than conventional inhaled steroids.[297-301] The clinical benefit of this is not clear as the exact efficacy to safety ratio compared to other inhaled steroids has not been fully established.

Non-CFC beclometasone is available in more than one preparation, and the potency relative to CFC beclometasone is not consistent between these *(see section 5.4)*.

4.2.2 INHALED STEROIDS

Inhaled steroids are the most effective preventer drug for adults and older children for achieving overall treatment goals.[278-282] There is an increasing body of evidence demonstrating that, at recommended doses, they are also safe and effective in children under five years with asthma.[283-286]

>12 years	5-12 years	<5 years
1++	1++	1++

Many non-atopic children with recurrent episodes of viral-induced wheezing in children under five years do not go on to have chronic atopic asthma. The majority do not require treatment with regular inhaled steroids *(see section 2.1)*.

A	A	A	**Inhaled steroids are the recommended preventer drug for adults and children for achieving overall treatment goals.**

Inhaled steroids should be considered for adults, children aged 5-12 and children under the age of five with any of the following features: using inhaled β_2 agonists three times a week or more; symptomatic three times a week or more; or waking one night a week. In addition, inhaled steroids should be considered in adults and children aged 5-12 who have had an exacerbation of asthma requiring oral corticosteroids in the last two years.[287,288 767-769]

>12 years	5-12 years	<5 years
1+	1+	1+

Inhaled steroids should be considered for patients with any of the following asthma-related features:

B	C	■	**exacerbations of asthma in the last two years**
B	B	B	**using inhaled β_2 agonists three times a week or more**
B	B	B	**symptomatic three times a week or more**
B	C	☑	**waking one night a week.**

Starting dose of inhaled steroids

In mild to moderate asthma, starting at very high doses of inhaled steroids and stepping down confers no benefit.[289]

>12 years	5-12 years	<5 years
1+	1+	

☑ Start patients at a dose of inhaled steroids appropriate to the severity of disease.

☑ In adults, a reasonable starting dose will usually be 400 mcg BDP per day and in children 200 mcg BDP per day. In children under five years, higher doses may be required if there are problems in obtaining consistent drug delivery.

☑ Titrate the dose of inhaled steroid to the lowest dose at which effective control of asthma is maintained.

Frequency of dosing of inhaled steroids

Most current inhaled steroids are slightly more effective when taken twice rather than once daily, but may be used once daily in some patients with milder disease.[273,279,290,767,770]

>12 years	5-12 years	<5 years
1+	1+	1+

There is little evidence of benefit for dosage frequency more than twice daily.[279]

A	D	D	**Give inhaled steroids initially twice daily, except ciclesonide which is given once daily.**
A	D	D	**Once a day inhaled steroids at the same total daily dose can be considered if good control is established.**

4.2.3 SAFETY OF INHALED STEROIDS

The safety of inhaled steroids is of crucial importance and a balance between benefits and risks for each individual needs to be assessed. Account should be taken of other topical steroid therapy when assessing systemic risk. It has been suggested that steroid warning cards should be issued to patients on higher dose inhaled steroids, but the benefits and possible disadvantages, particularly with regard to compliance, of such a policy remain to be defined.

Adults

There is little evidence that doses below 800 mcg BDP per day cause any short term detrimental effects apart from the local side effects of dysphonia and oral candidiasis. However, the possibility of long term effects on bone has been raised. One systematic review reported no effect on bone density at doses up to 1,000 mcg BDP per day.[291] The significance of small biochemical changes in adrenocortical function is unknown.

☑ Titrate the dose of inhaled steroid to the lowest dose at which effective control of asthma is maintained.

Children

Administration of inhaled steroids at or above 400 mcg BDP a day or equivalent may be associated with systemic side effects.[292] These may include growth failure and adrenal suppression. Isolated growth failure is not a reliable indicator of adrenal suppression and monitoring growth cannot be used as a screening test of adrenal function.[290,293]

Clinical adrenal insufficiency has been identified in a small number of children who have become acutely unwell at the time of intercurrent illness. Most of these children had been treated with high doses of inhaled corticosteroids. The dose or duration of inhaled steroid treatment required to place a child at risk of clinical adrenal insufficiency is unknown but is likely to occur at ≥800 mcg BDP per day or equivalent. The low-dose ACTH test is considered to provide a physiological stimulation of adrenal responsiveness but it is not known how useful such a sensitive test is at predicting clinically relevant adrenal insufficiency.[59,294] In addition, it is unknown how frequently tests of adrenal function would need to be repeated if a child remained on high-dose inhaled corticosteroid. At higher doses, add-on agents, for example, long-acting β_2 agonists, should be actively considered.

2009 While the use of inhaled corticosteroids may be associated with adverse effects (including the potential to reduced bone mineral density) with careful inhaled steroid dose adjustment this risk is likely to be outweighed by their ability to reduce the need for multiple bursts of oral corticosteroids.[771]

☑ Monitor height of children on high doses of inhaled steroids on a regular basis.

☑ The lowest dose of inhaled steroids compatible with maintaining disease control should be used.

For children treated with ≥800 mcg BDP per day or equivalent:

☑ Specific written advice about steroid replacement (eg Steroid Alert Card) in the event of a severe intercurrent illness or surgery should be part of the management plan.

☑ The child should be under the care of a specialist paediatrician for the duration of the treatment.

Consider the possibility of adrenal insufficiency in any child maintained on inhaled steroids presenting with shock or a decreased level of consciousness; serum biochemistry and blood glucose levels should be checked urgently. Consider whether intramuscular (IM) hydrocortisone is required.

4.2.4 SMOKING

Current and previous smoking reduces the effect of inhaled steroids; which may be overcome with increased doses.[187,302]

Patients should be advised that smoking reduces the effectiveness of therapy.

B **Clinicians should be aware that higher doses of inhaled steroids may be needed in patients who are smokers or ex-smokers.**

4.2.5 OTHER PREVENTER THERAPIES

Inhaled steroids are the first choice preventer drug. Long-acting inhaled β_2 agonists should not be used without inhaled corticosteroids.[303] Alternative, less effective preventer therapies in patients taking short-acting β_2 agonists alone are:

	>12 years	5-12 years	<5 years
▪ Chromones			
- Sodium cromoglicate is of some benefit in adults[273, 304] and is effective in children aged 5-12[305]	1^+	1^+	
- Nedocromil sodium is also of benefit in adults and children >5[306,307]	1^{++}	1^+	
- There is no clear evidence of benefit with sodium cromoglicate in children aged <5[308]			
▪ Leukotriene receptor antagonists have some beneficial clinical effect[279,309,310]	1^{++}	1^{++}	1^{++}
▪ Theophyllines have some beneficial effect[273,278]	1^+	1^+	1^+
▪ Antihistamines and ketotifen are ineffective[311]	1^{++}	1^{++}	1^{++}

☑ In children under five years who are unable to take inhaled corticosteroids, leukotriene receptor antagonists are an effective first line preventor.

4.3 STEP 3: INITIAL ADD-ON THERAPY

A proportion of patients with asthma may not be adequately controlled at step 2. Before initiating a new drug therapy practitioners should recheck compliance, inhaler technique and eliminate trigger factors. The duration of a trial of add-on therapy will depend on the desired outcome. For instance, preventing nocturnal awakening may require a relatively short trial of treatment (days or weeks), whereas preventing exacerbations of asthma or decreasing steroid tablet use may require a longer trial of therapy (weeks or months). If there is no response to treatment the drug should be discontinued.

4.3.1 CRITERIA FOR INTRODUCTION OF ADD-ON THERAPY

	>12 years	5-12 years	<5 years
No exact dose of inhaled steroid can be deemed the correct dose at which to add another therapy. The addition of other treatment options to inhaled steroids has been investigated at doses from 200-1,000 mcg BDP in adults and up to 400 mcg BDP in children.[312-315] Many patients will benefit more from add-on therapy than from increasing inhaled steroids above doses as low as 200 mcg BDP/day. At doses of inhaled steroid above 800 mcg BDP/day side effects become more frequent. An absolute threshold for introduction of add-on therapy in all patients cannot be defined.	1^+	1^+	

4.3.2 ADD-ON THERAPY

	>12 years	5-12 years	<5 years
Options for add-on therapy are summarised in Figure 3.			
In adult patients taking inhaled steroids at doses of 200-800 mcg BDP/day and in children taking inhaled steroids at a dose of 400 mcg/day the following interventions are of value:			
▪ first choice would be the addition of an inhaled long-acting β_2 agonist (LABA), which improves lung function and symptoms, and decreases exacerbations.[312,316,317]	1^{++}	1^{++}	

A B

The first choice as add-on therapy to inhaled steroids in adults and children *(5-12 years)* **is an inhaled long-acting β_2 agonist, which should be considered before going above a dose of 400 mcg BDP or equivalent per day and certainly before going above 800 mcg BDP.**

B

The first choice as add-on therapy to inhaled steroids in children under five years old is leukotriene receptor antagonists.

If, as occasionally happens, there is no response to inhaled long-acting β_2 agonist, stop the LABA and increase the dose of inhaled steroid to 800 mcg BDP/day *(adults)* or 400 mcg BDP/day *(children)* if not already on this dose. If there is a response to LABA, but control remains suboptimal, continue with the LABA and increase the dose of inhaled steroid to 800 mcg/day (adults) or 400 mcg/day (children 5-12 years).[318]

>12 years	5-12 years	<5 years
4	4	

D D

If asthma control remains suboptimal after the addition of an inhaled long-acting β_2 agonist then the dose of inhaled steroids should be increased to 800 mcg/day in adults or 400 mcg/day in children *(5-12 years)***, if not already on these doses.**

>12 years	5-12 years	<5 years
1^{++}	1^{++}	1^{+}
1^{+}	1^{-}	
1^{++}		

- **Leukotriene receptor antagonists** may provide improvement in lung function, a decrease in exacerbations, and an improvement in symptoms.[310,319,320]
- **Theophyllines** may improve lung function and symptoms, but side effects occur more commonly.[313]
- **Slow-release β_2 agonist tablets** may also improve lung function and symptoms, but side effects occur more commonly.[312]

☑ If control remains inadequate after stopping a LABA and increasing the dose of inhaled steroid, consider sequential trials of add-on therapy, ie leukotriene receptor antagonists, theophyllines, slow-release β_2 agonist tablets *(this in adults only)*.

Addition of short-acting anticholinergics is generally of no value.[314,321] Addition of nedocromil is of marginal benefit.[304,315]

>12 years	5-12 years	<5 years
1^{+}		

2009

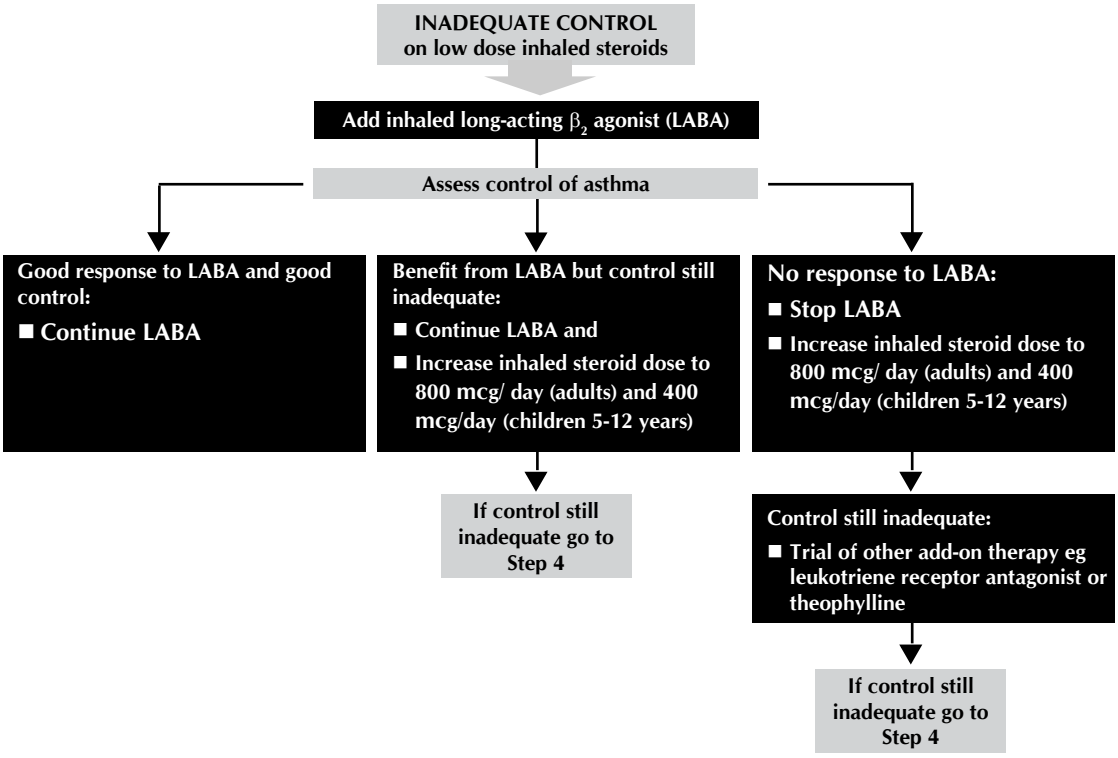
In selected adult patients at step 3 who are poorly controlled or in selected adult patients at step 2 (above BDP 400 mcg/day who are poorly controlled), the use of budesonide/formoterol in a single inhaler as rescue medication instead of a short-acting β_2 agonist, in addition to its regular use as controller therapy has been shown to be an effective treatment regimen.[323-327] When this management option is introduced the total regular dose of daily inhaled corticosteroids should not be decreased. The regular maintenance dose of inhaled steroids may be budesonide 200 mcg twice daily or budesonide 400 mcg twice daily. Patients taking rescue budesonide/formoterol once a day or more should have their treatment reviewed. Careful education of patients about the specific issues around this management strategy is required.

In patients on inhaled steroids whose asthma is stable, no intervention has been consistently shown to decrease inhaled steroid requirement in a clinically significant manner compared to placebo.

The Medicines and Healthcare products Regulatory Agency (MHRA) has completed a full review of the balance of risks and benefits associated with long-acting β_2 agonists in the management of asthma and chronic obstructive pulmonary disease.[322] They have concluded that long-acting β_2 agonists can continue to be used in the management of asthma provided they are used with inhaled corticosteroids. This issue has been reviewed by the guideline development group, which came to the same conclusion.

☑ Long-acting inhaled β_2 agonists should only be started in patients who are already on inhaled corticosteroids.

Figure 3: Summary of step 3: Add-on therapy



4.3.3 COMBINATION INHALERS

>12 years	5-12 years	<5 years
1++	1++	

There is no difference in efficacy in giving inhaled steroid and long-acting β_2 agonist in combination or in separate inhalers.[318]

Once a patient is on stable therapy, combination inhalers have the advantage of guaranteeing that the long-acting β_2 agonist is not taken without inhaled steroid.

4.4 STEP 4: POOR CONTROL ON MODERATE DOSE OF INHALED STEROID + ADD-ON THERAPY: ADDITION OF FOURTH DRUG

In a small proportion of patients asthma is not adequately controlled on a combination of short-acting β_2 agonist as required, inhaled steroid (800 mcg BDP daily), and an additional drug, usually a long-acting β_2 agonist. There are very few clinical trials in this specific patient group to guide management. The following recommendations are largely based on extrapolation from trials of add-on therapy to inhaled steroids alone.

D D

If control remains inadequate on 800 mcg BDP daily *(adults)* **and 400 mcg daily** *(children)* **of an inhaled steroid plus a long-acting β_2 agonist, consider the following interventions:**

- **increasing inhaled steroids to 2000 mcg BDP/day** *(adults)* **or 800 mcg BDP/day** *(children 5-12 years)* *****
- **leukotriene receptor antagonists**
- **theophyllines**
- **slow release β_2 agonist tablets, though caution needs to be used in patients already on long-acting β_2 agonists.**

* at high doses of inhaled steroid via MDI, a spacer should be used.

There are no controlled trials indicating which of these is the best option, although the potential for side effects is greater with theophyllines and β_2 agonist tablets.

☑ If a trial of an add-on treatment is ineffective, stop the drug (or in the case of increased dose of inhaled steroid, reduce to the original dose).

☑ Before proceeding to step 5, refer patients with inadequately controlled asthma, especially children, to specialist care.

4.5 STEP 5: CONTINUOUS OR FREQUENT USE OF ORAL STEROIDS

☑ For the small number of patients not controlled at step 4, use daily steroid tablets in the lowest dose providing adequate control.

4.5.1 PREVENTION AND TREATMENT OF STEROID TABLET-INDUCED SIDE EFFECTS

Patients on long term steroid tablets (eg longer than three months) or requiring frequent courses of steroid tablets (eg three to four per year) will be at risk of systemic side effects.[59]

- blood pressure should be monitored
- urine or blood sugar and cholesterol should be checked. Diabetes mellitus and hyperlipidaemia may occur
- bone mineral density should be monitored. When a significant reduction occurs, treatment with a long-acting bisphosphonate should be offered (see British Osteoporosis Society guidelines, www.nos.org.uk)[328]
- growth (height and weight) should be monitored in children
- cataracts may be screened for in children through community optometric services.

4.5.2 STEROID TABLET-SPARING MEDICATION

The aim of treatment is to control the asthma using the lowest possible dose or, if possible, to stop long term steroid tablets completely.

Inhaled steroids are the most effective drug for decreasing requirement for long term steroid tablets.[280,281]

>12 years	5-12 years	<5 years
1++	4	

There is limited evidence for the ability of long-acting β_2 agonists, theophyllines, or leukotriene receptor antagonists to decrease requirement for steroid tablets, but they may improve symptoms and pulmonary function.[329]

A D

In adults, the recommended method of eliminating or reducing the dose of steroid tablets is inhaled steroids, at doses of up to 2,000 mcg/day, if required.

In children aged 5-12, consider very carefully before going above an inhaled steroid dose of 800 mcg/day.

D D D

There is a role for a trial of treatment with long acting β_2 agonists, leukotriene receptor antagonists, and theophyllines for about six weeks. They should be stopped if no improvement in steroid dose, symptoms or lung function is detected.

Immunosuppressants (methotrexate, ciclosporin and oral gold) decrease long term steroid tablet requirements, but all have significant side effects. There is no evidence of persisting beneficial effect after stopping them; and there is marked variability in response.[330]

>12 years	5-12 years	<5 years
1++	3	

☑ Immunosuppressants (methotrexate, ciclosporin and oral gold) may be given as a three month trial, once other drug treatments have proved unsuccessful. Their risks and benefits should be discussed with the patient and their treatment effects carefully monitored. Treatment should be in a centre with experience of using these medicines.

	>12 years	5-12 years	<5 years
Colchicine and intravenous immunoglobulin have not been shown to have any beneficial effect in adults.[330]	1+		
Continuous subcutaneous terbutaline infusion has been reported to be beneficial in severe asthma but efficacy and safety have not been assessed in RCTs.[331,332,772,773]	4	3	3
Anti-TNF alpha therapy has been investigated in severe asthma [333,334] but these studies are too small and too short term to allow recommendation of anti-TNF therapy outside the context of a controlled clinical trial.			

4.5.3 ANTI-IGE MONOCLONAL ANTIBODY

Omalizumab is a humanised monoclonal antibody which binds to circulating IgE, markedly reducing levels of free serum IgE.[774,775] In adults and children over 12, it is licensed in the UK with the following indication; patients on high-dose inhaled steroids and long-acting β_2 agonists who have impaired lung function are symptomatic with frequent exacerbations, and have allergy as an important cause of their asthma. Omalizumab is given as a subcutaneous injection every two to four weeks depending on dose. The total IgE must be less than 700 iu/litre for it to be effective.

In the single study in the licensed group, there was a 19% reduction in exacerbations of asthma requiring oral steroids which was non-significant. When corrected for imbalance in the exacerbation history at baseline, there was a 26% reduction in severe exacerbations (0.91 on placebo vs 0.68 on omalizumab over a 28 week period, $p = 0.042$). This was associated with a 2.8% increase in FEV_1, a non-significant 0.5 puffs/day decrease in β_2 agonist use and 13% more patients having a significant improvement in health related quality of life. At IgE levels below 76 iu/l the beneficial effect is reduced.[776]	1-

Local skin reactions may occur. Anaphylaxis, presenting as bronchospasm, hypotension, syncope, urticaria, and/or angioedema of the throat or tongue has been reported to occur after administration of omalizumab. Anaphylaxis has occurred as early as the first dose, but has also occurred after one year. Due to risk of anaphylaxis, omalizumab should only be administered to patients in a healthcare setting under direct medical supervision.

☑ Omalizumab treatment should only be initiated in specialist centres with experience of evaluation and management of patients with severe and difficult asthma.

4.5.4 STEROID FORMULATIONS

Prednisolone is the most widely used steroid tablet for maintenance therapy in chronic asthma. There is no evidence that other formulations offer any advantage.

4.5.5 FREQUENCY OF DOSING OF STEROID TABLETS

Although popular in paediatric practice, there are no studies to show whether alternate day steroids produce fewer side effects than daily steroids.

Figure 4: Summary of stepwise management in adults

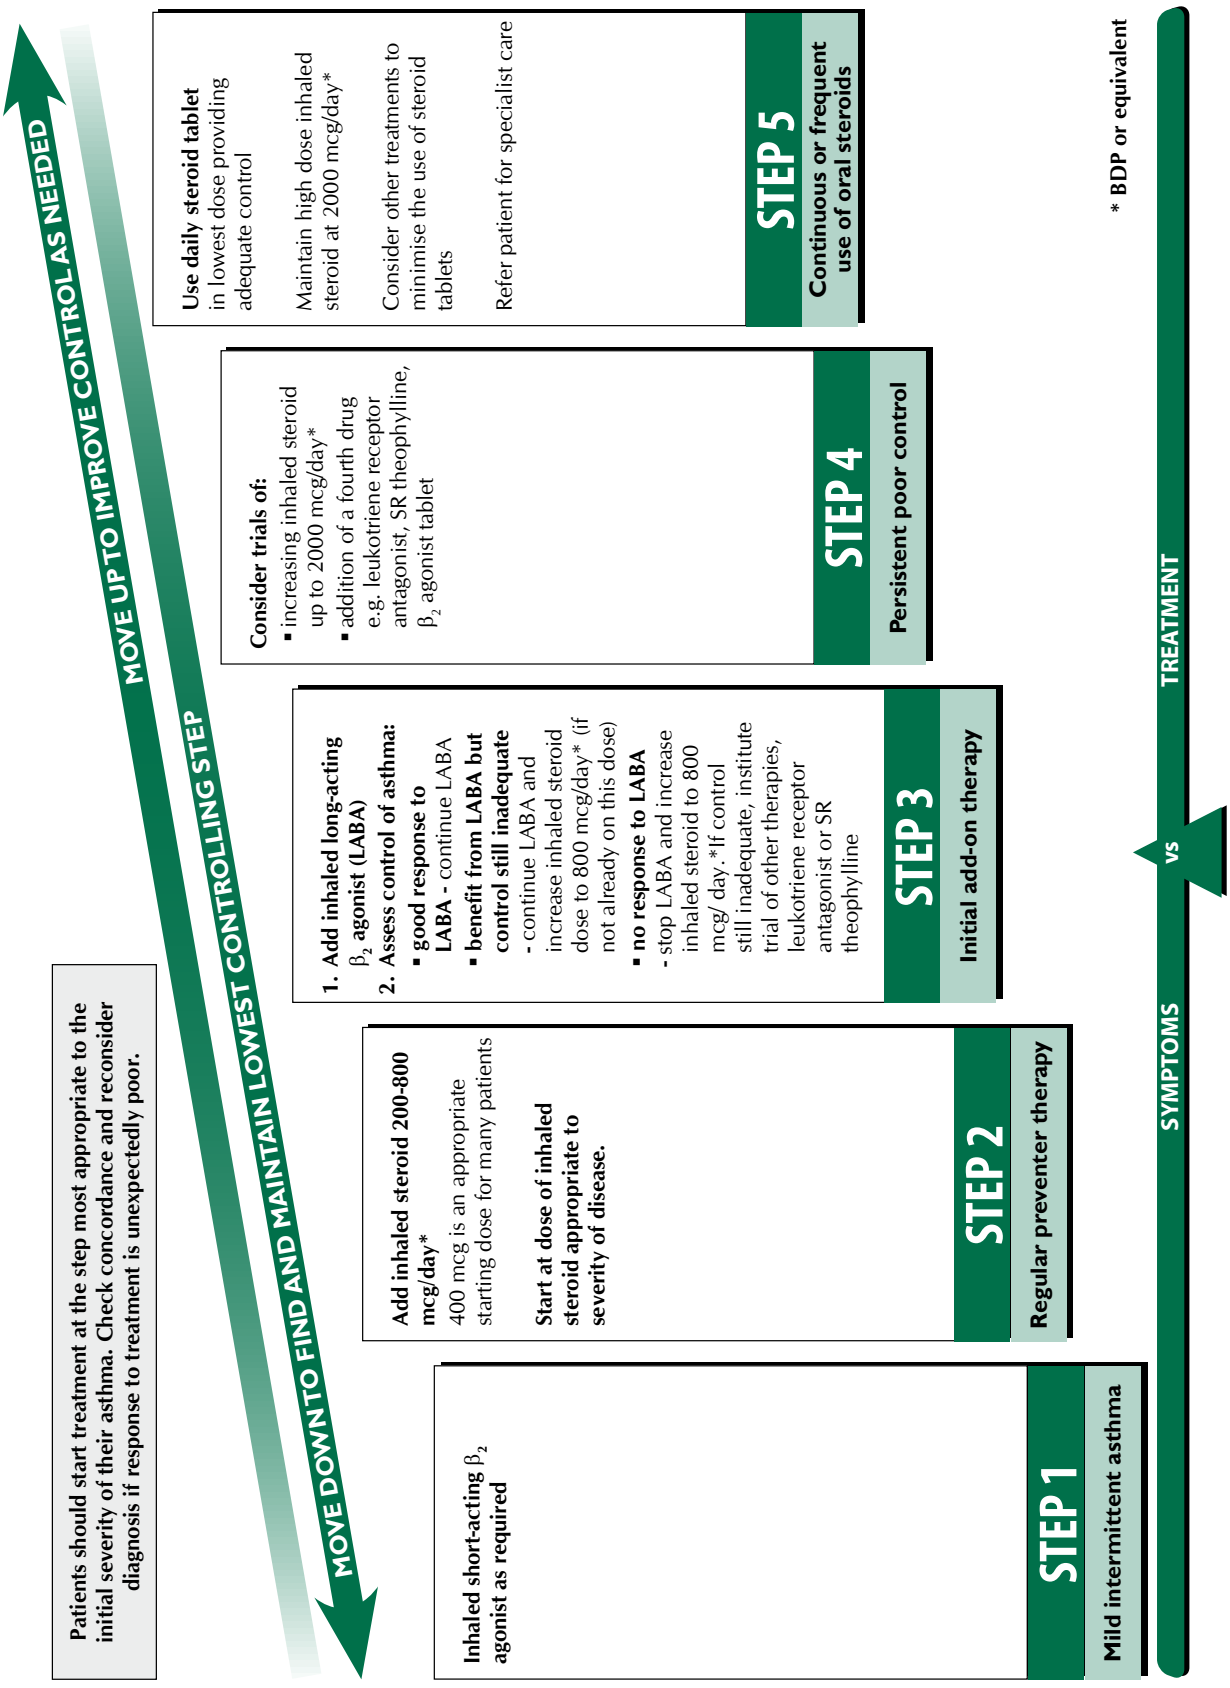


Figure 5: Summary of stepwise management in children aged 5-12 years

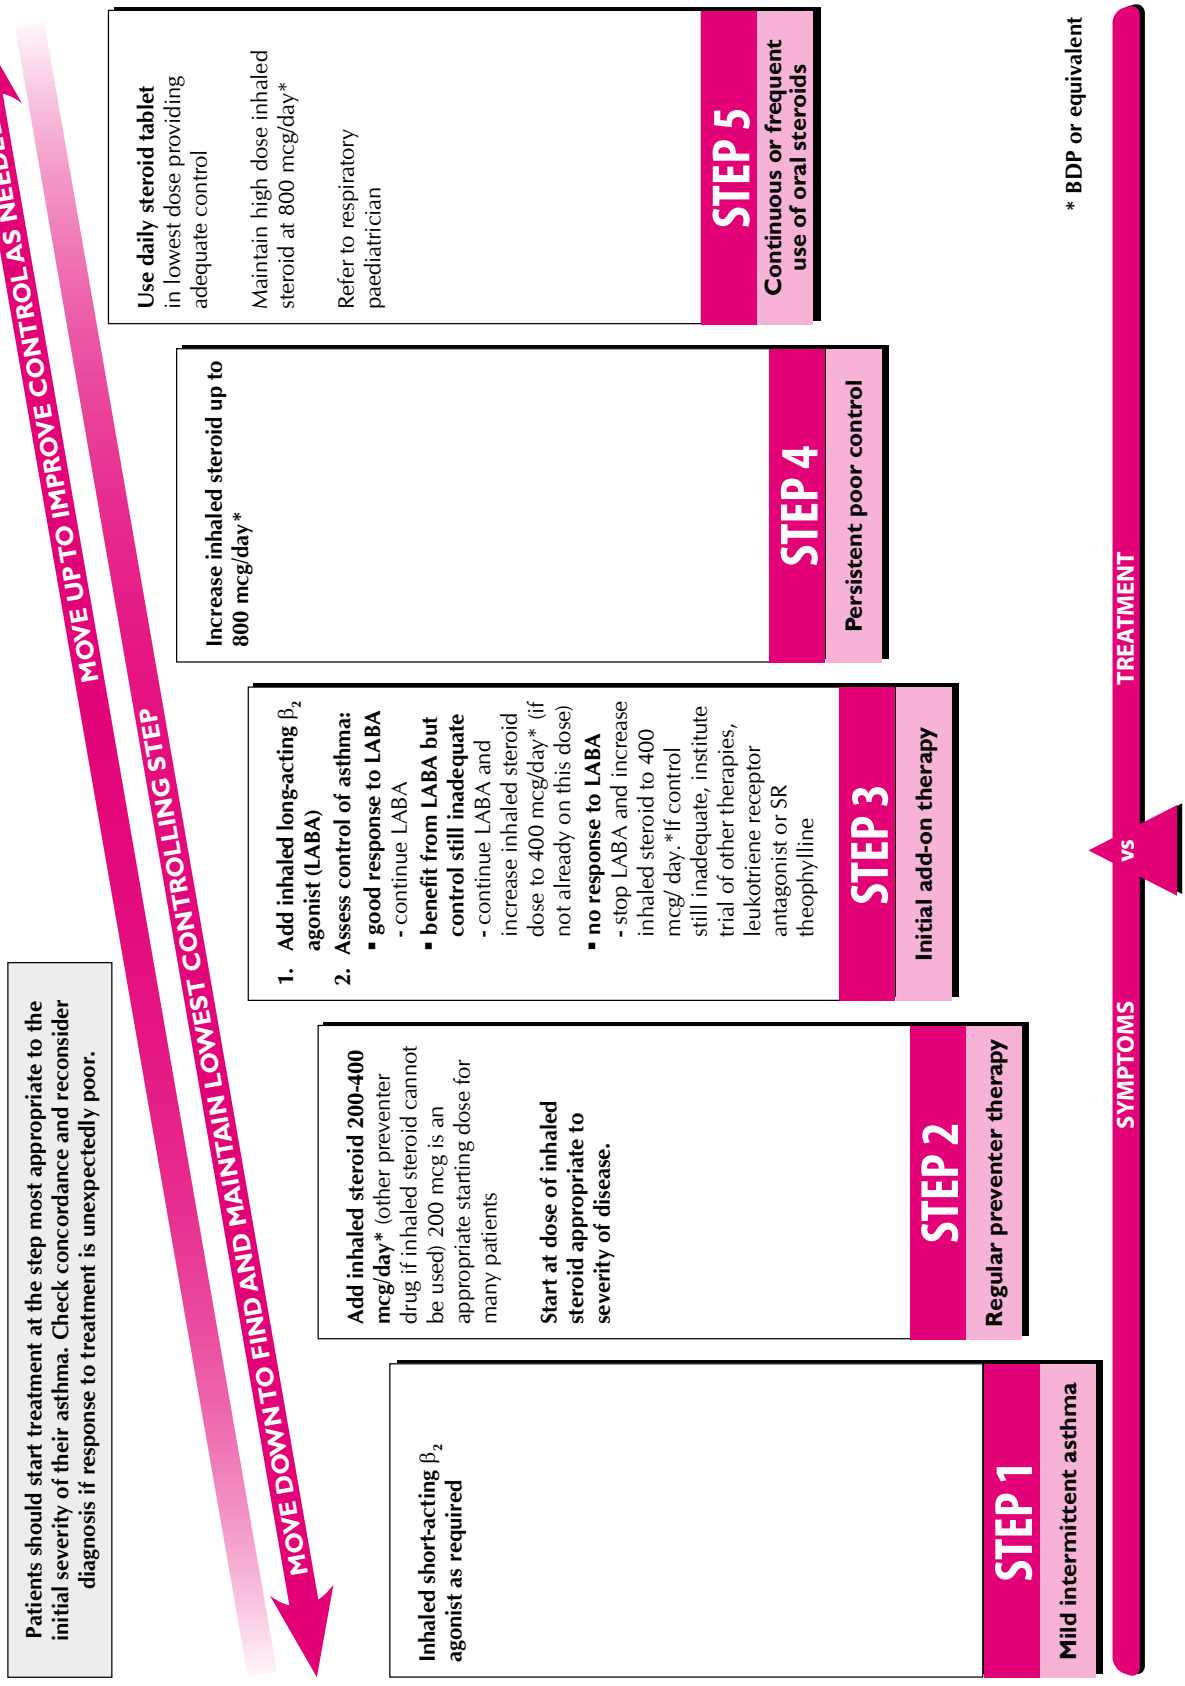

Figure 6: Summary of stepwise management in children less than 5 years

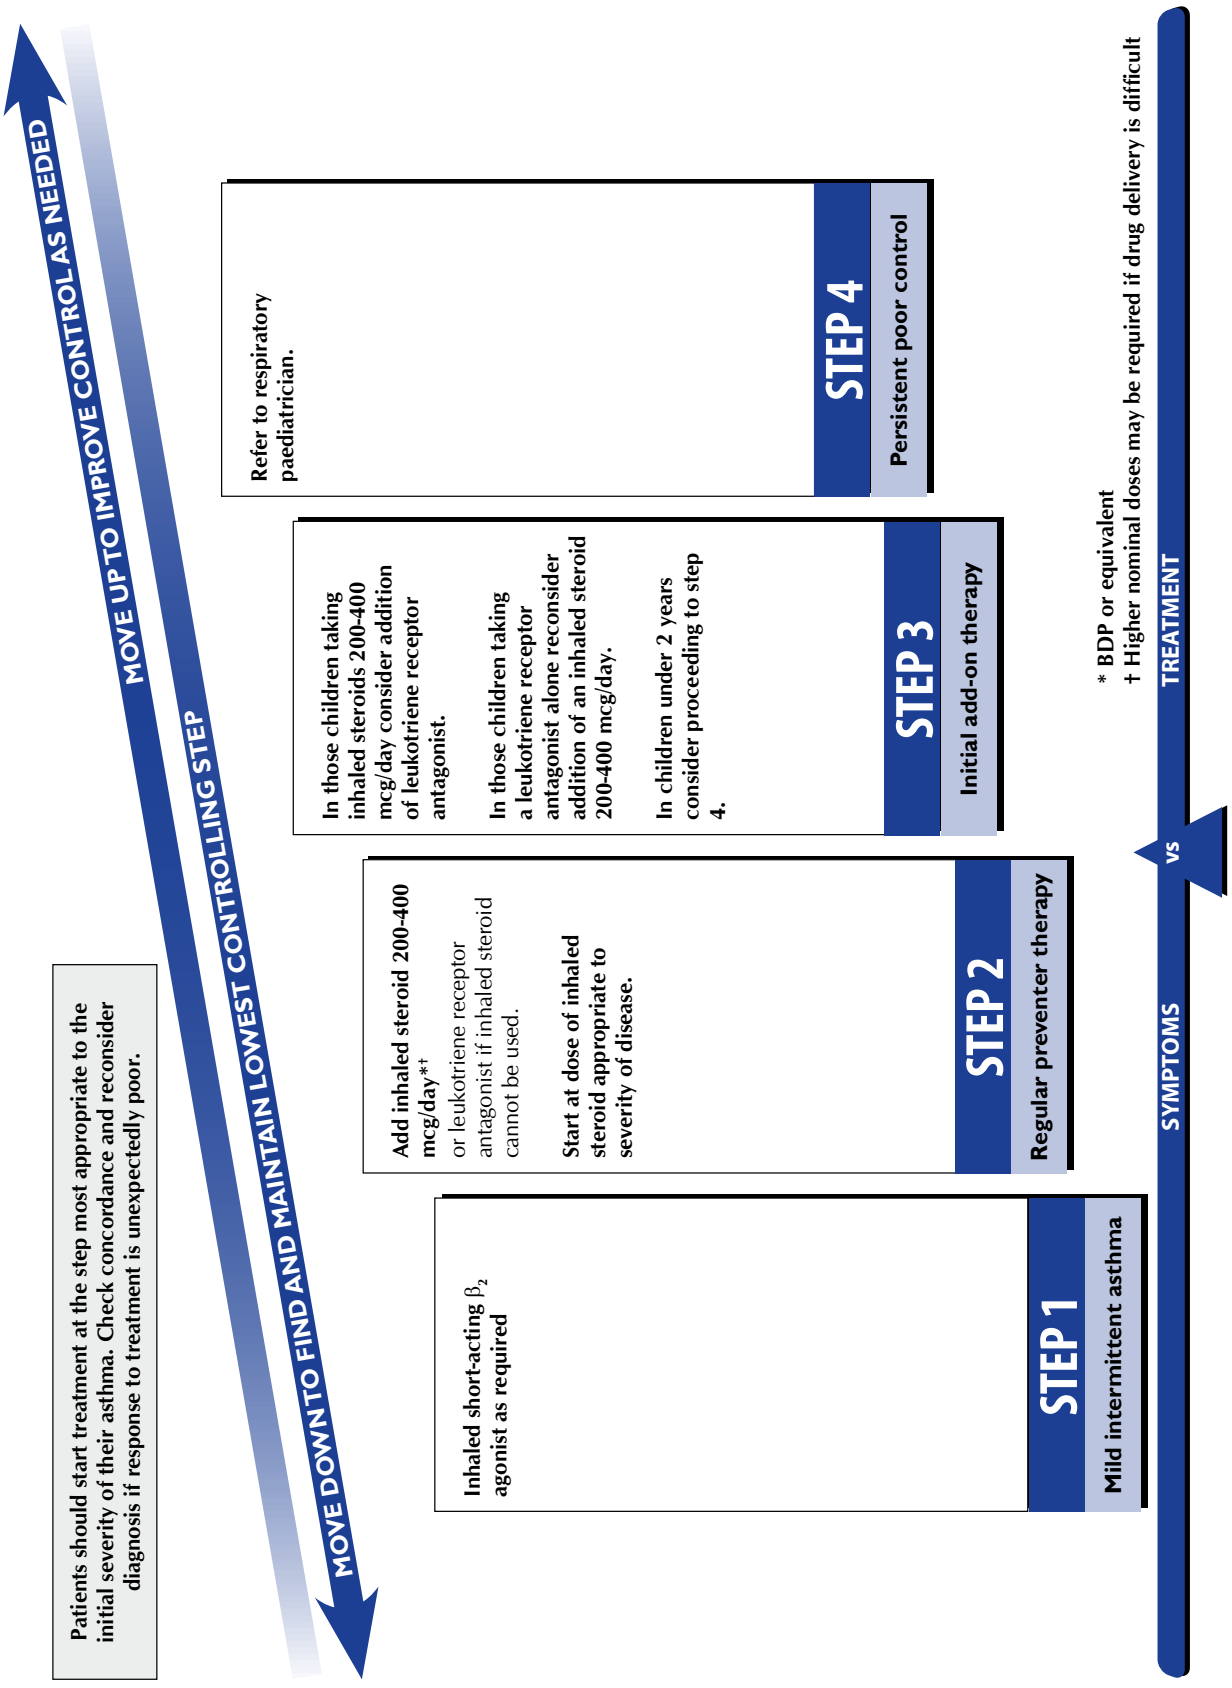


4.6 STEPPING DOWN

Stepping down therapy once asthma is controlled is recommended, but often not implemented leaving some patients over-treated. There are few studies that have investigated the most appropriate way to step down treatment. A study in adults on at least 900 mcg per day of inhaled steroids has shown that for patients who are stable it is reasonable to attempt to halve the dose of inhaled steroids every three months.[334]

2009 Some children with milder asthma and a clear seasonal pattern to their symptoms may have a more rapid dose reduction during their 'good' season.

☑ Regular review of patients as treatment is stepped down is important. When deciding which drug to step down first and at what rate, the severity of asthma, the side effects of the treatment, time on current dose, the beneficial effect achieved, and the patient's preference should all be taken into account.

☑ Patients should be maintained at the lowest possible dose of inhaled steroid. Reduction in inhaled steroid dose should be slow as patients deteriorate at different rates. Reductions should be considered every three months, decreasing the dose by approximately 25-50% each time.

4.7 SPECIFIC MANAGEMENT ISSUES

4.7.1 EXACERBATIONS OF ASTHMA

Although recommended for both adults and children in previous guidelines and as part of asthma action plans, doubling the dose at the time of an exacerbation is of unproven value.[335] In adult patients on a low dose (200 mcg BDP) of inhaled steroids, a fivefold increase in dose at the time of exacerbation leads to a decrease in the severity of exacerbations.[335,336] This study should not be extrapolated to patients already taking higher doses of inhaled steroids and further evidence in this area is required.

	>12 years	5-12 years	<5 years
2009 There is some limited evidence that leukotriene antagonists may be used intermittently in children with episodic asthma. Treatment is started at the onset of either asthma symptoms or of coryzal symptoms and continued for seven days.[777]		1^{++}	1^{++}

The benefits of parent-initiated oral steroids at the start of an exacerbation has not been proven.[778]

4.7.2 EXERCISE INDUCED ASTHMA

When given chronically the following medicines give protection against exercise induced asthma:	>12 years	5-12 years	<5 years
▪ inhaled steroids[280, 281,337]	1^{++}	1^{++}	
▪ short-acting β_2 agonists[273]	1^{++}	1^{++}	
▪ long-acting β_2 agonists[338]	1^{++}	1^{++}	
▪ theophyllines[329,339]	1^{-}	2^{+}	
▪ leukotriene receptor antagonists[340]	1^{++}	2^{+}	
▪ chromones[341]	1^{++}	2^{+}	
▪ β_2 agonist tablets.[342]	1^{++}	1^{+}	
The following medicines do not give protection against exercise induced asthma at normal doses:			
▪ anticholinergics[343]	1^{+}	1^{+}	
▪ ketotifen[344]	1^{+}	1^{+}	
▪ antihistamine.[345]	1^{++}	1^{++}	

Long-acting β_2 agonists and leukotriene antagonists provide more prolonged protection than short-acting β_2 agonists, but a degree of tolerance develops with LABA particularly with respect to duration of action. No tolerance has been demonstrated with leukotriene receptor antagonists.[338,340,779]	>12 years	5-12 years	<5 years
	1^{++}	1^{++}	

☑ For most patients, exercise induced asthma is an expression of poorly controlled asthma and regular treatment including inhaled steroids should be reviewed.

If exercise is a specific problem in patients taking inhaled steroids who are otherwise well controlled, consider the following therapies:

A C ▪ **leukotriene receptor antagonists**

A A ▪ **long-acting β_2 agonists**

C C ▪ **chromones**

A A ▪ **oral β_2 agonists**

C C ▪ **theophyllines.**

Immediately prior to exercise, inhaled short-acting β_2 agonists are the drug of choice.[273]

A A **Immediately prior to exercise, inhaled short-acting β_2 agonists are the drug of choice.**

4.7.3 RHINITIS

Patients with asthma often have rhinitis. The most effective therapy is intranasal steroids.[346] Treatment of allergic rhinitis with intranasal steroids has not been shown in double blind placebo-controlled trials to improve asthma control.

>12 years	5-12 years	<5 years
1+		

4.7.4 ALLERGIC BRONCHOPULMONARY ASPERGILLOSIS

In adult patients with allergic bronchopulmonary aspergillosis (ABPA), itraconazole may decrease steroid tablet dose and improve asthma control.[347,348]

>12 years	5-12 years	<5 years
1+ 2+		

C **In adult patients with ABPA, a four month trial of itraconazole should be considered.**

☑ Careful monitoring for side effects, particularly hepatic, is recommended.

4.7.5 ASPIRIN-INTOLERANT ASTHMA

There are theoretical reasons to suggest that leukotriene receptor antagonists might be of particular value in the treatment of aspirin-intolerant asthma. However, there is little evidence to justify managing patients with aspirin-intolerant asthma in a different manner to other patients with asthma, apart from the rigorous avoidance of non-steroidal anti-inflammatory medications.[349]

4.7.6 GASTRO-OESOPHOGEAL REFLUX

A Cochrane review of twelve double blind controlled trials found that treatment of gastro-oesophageal reflux had no benefit on asthma symptoms or lung function when both conditions were present. Reduction in dry cough was observed although this was probably not due to improved asthma control.[350,351]

4.7.7 β-BLOCKERS

β-blockers, including eye drops, are contraindicated in patients with asthma.

5 Inhaler devices

Although studies of inhaler devices are more suitable for an evidence based approach than many other aspects of asthma management, a number of methodological issues complicate evidence review in this area. In young (0-5 years) children, little or no evidence is available on which to base recommendations.

5.1 TECHNIQUE AND TRAINING

Studies of technique and the effects of training have used arbitrary non-standardised scores making comparison difficult. Although technique will have some bearing, it does not necessarily relate to clinical effectiveness.

The proportion of patients making no mistakes with an inhaler in one well conducted study was 23-43% for pMDI, 53-59% for dry powder inhaler (DPI) and 55-57% for pMDI + spacer. When technique was assessed as number of steps correct out of the total number of steps, pMDI + spacer was slightly better than DPI.[352]

Teaching technique improved the correct usage score from a mean of 60% to 79%. Figures for no mistakes post-teaching were 63% for pMDI, 65% for DPI, and 75% for breath-actuated MDI (the latter figure based on one study of 2,467 patients).[352]

>12 years	5-12 years	<5 years
1++		

B ☑ ☑ **Prescribe inhalers only after patients have received training in the use of the device and have demonstrated satisfactory technique.**

5.2 β_2 AGONIST DELIVERY

5.2.1 ACUTE ASTHMA

pMDI + spacer is at least as good as a nebuliser at treating mild and moderate exacerbations of asthma in children and adults.[353-356]

>12 years	5-12 years	<5 years
1++	1++	

A A B **Children and adults with mild and moderate exacerbations of asthma should be treated by pMDI + spacer with doses titrated according to clinical response.**

There are no data to make recommendations in severe (life threatening) asthma.

5.2.2 STABLE ASTHMA

For children aged 0-5, there is no evidence comparing nebuliser and other inhalers and the data are insufficiently extensive or robust to draw conclusions for pMDI vs. DPI.

In children aged 5-12 there is no significant difference between pMDI and DPI. In adults there is no significant difference between pMDI + spacer and DPI. The lower pulse rate with pMDI v Turbohaler is the only difference with regard to side effects. Patients have been shown to prefer Turbohaler to pMDI.[352,357,358]

>12 years	5-12 years	<5 years
	1++	

A **In children aged 5-12, pMDI + spacer is as effective as any other hand held inhaler.**

A **In adults, pMDI ± spacer is as effective as any other hand held inhaler, but patients may prefer some types of DPI.**

There are no data to make recommendations in children under five.

☑ Choice of reliever inhaler for stable asthma should be based on patient preference and assessment of correct use. Many patients will not be prepared to carry a spacer.

5.3 INHALED STEROIDS FOR STABLE ASTHMA

There are no comparative data on inhaled steroids for stable asthma in children under five years. A single study included 4-5 year olds, but the data were not extractable.

For the delivery of inhaled steroids in stable asthma in children aged 5-12 years, pMDI is as effective as Clickhaler,[359,360] and Pulvinal is as effective as Diskhaler.[361] No significant clinical difference was found between pMDI and Turbohaler at half the dose for the same drug (budesonide).[352,362] This comparison cannot necessarily be made against other inhaled steroid /device combinations.

>12 years	5-12 years	<5 years

In adults, there is no clinical difference in effectiveness of pMDI ± spacer v DPI. Breath-actuated MDI is as effective as pMDI. More recent DPIs are as effective as older DPIs.[305] Nebulisers have not been shown to be superior to pMDI + spacer for delivery of inhaled steroids in chronic asthma. A specialised specific nebuliser may provide improved lung function and reduced rescue therapy use, but at high prescribed doses. Higher doses (>2 mg) are generally only licensed for use from a nebuliser.[352,362]

>12 years	5-12 years	<5 years
1++	1++	

[ ] [A] [ ] **In children aged 5-12 years, pMDI + spacer is as effective as any DPI.**

[A] [ ] [ ] **In adults, a pMDI ± spacer is as effective as any DPI.**

No recommendation can be given for nebulised therapy in children aged 5-12 years and there is no evidence relating to children aged <5 years.

5.4 CFC PROPELLANT PMDI VS HFA PROPELLANT PMDI

HFA pMDI salbutamol is as effective as CFC pMDI salbutamol at standard therapeutic doses.[359,363-368]

>12 years	5-12 years	<5 years
1++		

It is important to differentiate Qvar from other HFA beclametasone products. Many studies now show Qvar equivalence at half the dose of CFC BDP pMDI, whereas non-Qvar HFA BDP pMDI studies show equivalence at 1:1 dosing. [360,369-375]

HFA fluticasone is as effective as CFC fluticasone across the standard clinical dose range.[376-380]

>12 years	5-12 years	<5 years
1++		

[A] [ ] [ ] **Salbutamol HFA can be substituted for salbutamol CFC at 1:1 dosing.**

[A] [ ] [ ] **HFA BDP pMDI (Qvar) may be substituted for CFC BDP pMDI at 1:2 dosing. This ratio does not apply to reformulated HFA BDP pMDIs.**

[A] [ ] [ ] **Fluticasone HFA can be substituted for fluticasone CFC at 1:1 dosing.**

5.5 PRESCRIBING DEVICES

There is no evidence to dictate an order in which devices should be tested for those patients who cannot use pMDI. In the absence of evidence, the most important points to consider are patient preference and local cost.

☑
- The choice of device may be determined by the choice of drug.
- If the patient is unable to use a device satisfactorily an alternative should be found.
- The patient should have their ability to use an inhaler device assessed by a competent healthcare professional *(see section 5.1)*.
- The medication needs to be titrated against clinical response to ensure optimum efficacy.
- Reassess inhaler technique as part of structured clinical review *(see section 8.1.2)*.

☑ In children aged 0-5 years, pMDI and spacer are the preferred method of delivery of β_2 agonists or inhaled steroids. A face mask is required until the child can breathe reproducibly using the spacer mouthpiece. Where this is ineffective a nebuliser may be required.

5.6 USE AND CARE OF SPACERS

☑
- The spacer should be compatible with the pMDI being used.
- The drug should be administered by repeated single actuations of the metered dose inhaler into the spacer, each followed by inhalation.
- There should be minimal delay between pMDI actuation and inhalation.
- Tidal breathing is as effective as single breaths.
- Spacers should be cleaned monthly rather than weekly as per manufacturer's recommendations or performance is adversely affected. They should be washed in detergent and allowed to dry in air. The mouthpiece should be wiped clean of detergent before use.
- Drug delivery may vary significantly due to static charge. Metal and other antistatic spacers are not affected in this way.
- Plastic spacers should be replaced at least every 12 months but some may need changing at six months.

Revised 2009

6 Management of acute asthma

6.1 LESSONS FROM STUDIES OF ASTHMA DEATHS AND NEAR-FATAL ASTHMA

Confidential enquires into over 200 asthma deaths in the UK conclude there are factors associated with the disease, the medical management and the patient's behaviour or psychosocial status which contribute to death. Most deaths occurred before admission to hospital.[381-385]

6.1.1 DISEASE FACTORS

Most patients who died of asthma had chronically severe asthma. In a minority the fatal attack occurred suddenly in a patient with mild or moderately severe background disease.[381-386] 2++

6.1.2 MEDICAL MANAGEMENT

Many of the deaths occurred in patients who had received inadequate treatment with inhaled steroid or steroid tablets and/or inadequate objective monitoring of their asthma. Follow up was inadequate in some and others should have been referred earlier for specialist advice. Asthma deaths are associated with fewer general practice contacts and more home visits.[780] There was widespread under-use of written management plans. Heavy or increasing use of β_2 agonist therapy was associated with asthma death.[381-385,387,388] 2++

2009 Deaths continue to be reported following inappropriate prescription of β-blockers and NSAIDs; all asthma patients should be asked about past reactions to these agents *(see section 4.7.7)*.

2009 Patients with acute asthma should not be sedated unless this is to allow anaesthetic or intensive care procedures (*see section 6.3.12*).[781]

6.1.3 ADVERSE PSYCHOSOCIAL AND BEHAVIOURAL FACTORS

Behavioural and adverse psychosocial factors were recorded in the majority of patients who died of asthma.[381-385] The most important are shown in Table 9.

Table 9: Patients at risk of developing near-fatal or fatal asthma

A COMBINATION OF SEVERE ASTHMA recognised by one or more of:
▪ previous near-fatal asthma, eg previous ventilation or respiratory acidosis ▪ previous admission for asthma especially if in the last year ▪ requiring three or more classes of asthma medication ▪ heavy use of β_2 agonist ▪ repeated attendances at ED for asthma care especially if in the last year ▪ "brittle" asthma.
AND ADVERSE BEHAVIOURAL OR PSYCHOSOCIAL FEATURES recognised by one or more of:
▪ non-compliance with treatment or monitoring ▪ failure to attend appointments ▪ fewer GP contacts ▪ frequent home visits ▪ self discharge from hospital ▪ psychosis, depression, other psychiatric illness or deliberate self harm ▪ current or recent major tranquilliser use ▪ denial ▪ alcohol or drug abuse ▪ obesity ▪ learning difficulties ▪ employment problems ▪ income problems ▪ social isolation ▪ childhood abuse ▪ severe domestic, marital or legal stress.

2009

Case control studies support most of these observations.[389,390] Compared with control patients admitted to hospital with asthma, those who died were significantly more likely to have learning difficulties; psychosis or prescribed antipsychotic drugs; financial or employment problems; repeatedly failed to attend appointments or discharged themselves from hospital; drug or alcohol abuse; obesity; or a previous near-fatal attack. 2++

Compared with control patients with asthma in the community, patients who died had more severe disease; more likelihood of a hospital admission or visit to the ED for their asthma in the previous year; more likelihood of a previous near-fatal attack; poor medical management; failure to measure pulmonary function; and non-compliance.

B **Healthcare professionals must be aware that patients with severe asthma and one or more adverse psychosocial factors are at risk of death.**

Studies comparing near-fatal asthma with deaths from asthma have concluded that patients with near-fatal asthma have identical adverse factors to those described in table 9, and that these contribute to the near-fatal asthma attack.[391-393] Compared with patients who die, those with near-fatal asthma are significantly younger, are significantly more likely to have had a previous near-fatal asthma attack, are less likely to have concurrent medical conditions, are less likely to experience delay in receiving medical care, and more likely to have ready access to acute medical care. 2+

With near-fatal asthma it is advisable to involve a close relative when discussing future management.

Patients with brittle or difficult asthma should also be identified *(see sections 6.2.3 and 7.1.1 and Table 10)*.

☑ Keep patients who have had near-fatal asthma or brittle asthma under specialist supervision indefinitely.

6.1.4 SEASONAL FACTORS

In the UK there is a peak of asthma deaths in people aged up to 44 years in July and August and in December and January in older people.[391,394] | 2++

6.1.5 PREDICTION AND PREVENTION OF A SEVERE ASTHMA ATTACK

Most attacks of asthma severe enough to require hospital admission develop relatively slowly over a period of six hours or more. In one study, over 80% developed over more than 48 hours.[395-400] There is, therefore, time for effective action to reduce the number of attacks requiring hospitalisation. There are many similarities between patients who die from asthma, patients with near-fatal asthma and control patients with asthma who are admitted to hospital. | 2++

☑ A respiratory specialist should follow up patients admitted with severe asthma for at least one year after the admission.

6.2 ACUTE ASTHMA IN ADULTS

Annexes 2-4 contain algorithms summarising the recommended treatment for patients presenting with acute or uncontrolled asthma in primary care *(Annex 2)*, ED *(Annex 3)*, and hospital *(Annex 4)*.

6.2.1 RECOGNITION OF ACUTE ASTHMA

Definitions of increasing levels of severity of acute asthma exacerbations are provided in table 10.[322,401-405] Predicted PEF values[406] should be used only if the recent best PEF (within two years) is unknown. | 2+ 4

6.2.2 SELF TREATMENT BY PATIENTS DEVELOPING ACUTE OR UNCONTROLLED ASTHMA

Patients with asthma, and all patients with severe asthma, should have an agreed written action plan and their own peak flow meter, with regular checks of inhaler technique and compliance. They should know when and how to increase their medication and when to seek medical assistance. Asthma action plans can decrease hospitalisation for[407] and deaths from[408] asthma *(see section 9.1)*.

6.2.3 INITIAL ASSESSMENT

All possible initial contact personnel, eg practice receptionists, ambulance call takers, NHS Direct (England and Wales), NHS24 (Scotland), should be aware that asthma patients complaining of respiratory symptoms may be at risk and should have immediate access to a doctor or trained asthma nurse. The assessments required to determine whether the patient is suffering from an acute attack of asthma, the severity of the attack and the nature of treatment required are detailed in tables 10 and 11. It may be helpful to use a systematic recording process. Proformas have proved useful in the ED setting.[409]

Table 10: Levels of severity of acute asthma exacerbations

Near-fatal asthma	Raised $PaCO_2$ and/or requiring mechanical ventilation with raised inflation pressures[391-393]	
Life threatening asthma	Any one of the following in a patient with severe asthma:	
	Clinical signs	Measurements
	Altered conscious level	PEF < 33% best or predicted
	Exhaustion	SpO_2 < 92%
	Arrhythmia	PaO_2 < 8 kPa
	Hypotension	"normal" $PaCO_2$ (4.6–6.0 kPa)
	Cyanosis	
	Silent chest	
	Poor respiratory effort	
Acute severe asthma	Any one of: - PEF 33-50% best or predicted - respiratory rate ≥ 25/min - heart rate ≥ 110/min - inability to complete sentences in one breath	
Moderate asthma exacerbation	- Increasing symptoms - PEF > 50-75% best or predicted - no features of acute severe asthma	
Brittle asthma	- Type 1: wide PEF variability (> 40% diurnal variation for > 50% of the time over a period > 150 days) despite intense therapy - Type 2: sudden severe attacks on a background of apparently well controlled asthma	

6.2.4 PREVENTION OF ACUTE DETERIORATION

A register of patients at risk may help primary care health professionals to identify patients who are more likely to die from their asthma. A system should be in place to ensure that these patients are contacted if they fail to attend for follow up.

6.2.5 CRITERIA FOR REFERRAL

D **Refer to hospital any patients with features of acute severe or life threatening asthma.**

Other factors, such as failure to respond to treatment, social circumstances or concomitant disease, may warrant hospital referral.

Table 11: Initial assessment - the role of symptoms, signs and measurements

	Clinical features	Clinical features can identify some patients with severe asthma, eg severe breathlessness (including too breathless to complete sentences in one breath), tachypnea, tachycardia, silent chest, cyanosis, accessory muscle use, altered consciousness or collapse.[322, 401-405,782]	2+
2009		None of these singly or together is specific. Their absence does not exclude a severe attack.	
	PEF or FEV_1	Measurements of airway calibre improve recognition of the degree of severity, the appropriateness or intensity of therapy, and decisions about management in hospital or at home.[410, 411]	
2009		PEF or FEV_1 are useful and valid measures of airway calibre. PEF is more convenient in the acute situation.	2+
		PEF expressed as a percentage of the patient's previous best value is most useful clinically. PEF as a percentage of predicted gives a rough guide in the absence of a known previous best value. Different peak flow meters give different readings. Where possible the same or similar type of peak flow meter should be used.	
	Pulse oximetry	Measure oxygen saturation (SpO_2) with a pulse oximeter to determine the adequacy of oxygen therapy and the need for arterial blood gas (ABG) measurement. The aim of oxygen therapy is to maintain SpO_2 94-98%.[783]	
2009			
	Blood gases (ABG)	Patients with $SpO_2 < 92\%$ (irrespective of whether the patient is on air or oxygen) or other features of life threatening asthma require ABG measurement.[322, 401-403, 405,413] $SpO_2 < 92\%$ is associated with a risk of hypercapnea. Hypercapnea is not detected by pulse oximetry.[784] In contrast the risk of hypercapnea with $SpO_2 > 92\%$ is much less.[783]	2+ 4
2009			
	Chest X-ray	Chest X-ray is not routinely recommended in patients in the absence of: – suspected pneumomediastinum or pneumothorax – suspected consolidation – life threatening asthma – failure to respond to treatment satisfactorily – requirement for ventilation.	4
	Systolic paradox	Systolic paradox (*pulsus paradoxus*) is an inadequate indicator of the severity of an attack and should not be used.[322, 401-405,414]	2+

6.2.6 CRITERIA FOR ADMISSION

B **Admit patients with any feature of a life threatening or near-fatal attack.**[381-385, 391,393]

B **Admit patients with any feature of a severe attack persisting after initial treatment.**[381-385, 391,393]

C **Patients whose peak flow is greater than 75% best or predicted one hour after initial treatment may be discharged from ED unless they meet any of the following criteria, when admission may be appropriate:**

- **still have significant symptoms**
- **concerns about compliance**
- **living alone/socially isolated**
- **psychological problems**
- **physical disability or learning difficulties**
- **previous near-fatal or brittle asthma**
- **exacerbation despite adequate dose steroid tablets pre-presentation**
- **presentation at night**
- **pregnancy.**

Criteria for admission in adults are summarised in annexes 2 and 3.

6.3 TREATMENT OF ACUTE ASTHMA IN ADULTS

6.3.1 OXYGEN

2009 Many patients with acute severe asthma are hypoxaemic.[415-418] Supplementary oxygen should be given urgently to hypoxaemic patients, using a face mask, Venturi mask or nasal cannulae with flow rates adjusted as necessary to maintain SpO_2 of 94-98%.[783] | 2^+ 4

2009 Hypercapnea indicates the development of near-fatal asthma and the need for emergency specialist/anaesthetic intervention.

2009 C **Give supplementary oxygen to all hypoxaemic patients with acute severe asthma to maintain an SpO_2 level of 94-98%. Lack of pulse oximetry should not prevent the use of oxygen.**

2009 Oxygen-driven nebulisers are preferred for nebulising β_2 agonist bronchodilators because of the risk of oxygen desaturation while using air-driven compressors.[322,353,419] | 1^{++}

2009 Emergency oxygen should be available in hospitals, ambulances and primary care. A flow rate of 6 l/min is required to drive most nebulisers. Where oxygen cylinders are used, a high flow regulator must be fitted.[783] | 4

2009 The absence of supplemental oxygen should not prevent nebulised therapy from being administered when appropriate.[420] | 4

2009 A **In hospital, ambulance and primary care, nebulised β_2 agonist bronchodilators should preferably be driven by oxygen.**

6.3.2 β_2 AGONIST BRONCHODILATORS

2009 In most cases inhaled β_2 agonists given in high doses act quickly to relieve bronchospasm with few side effects.[421-423] There is no evidence for any difference in efficacy between salbutamol and terbutaline. Nebulised adrenaline (epinephrine), a non-selective β_2 agonist, does not have significant benefit over salbutamol or terbutaline.[785] | 1^+ 1++

In acute asthma without life threatening features, β_2 agonists can be administered by repeated activations of a pMDI via an appropriate large volume spacer or by wet nebulisation driven by oxygen, if available.[786] Inhaled β_2 agonists are as efficacious and preferable to intravenous β_2 agonists (meta-analysis has excluded subcutaneous trials) in adult acute asthma in the majority of cases.[424] 1++

Metered dose inhalers with spacers can be used for patients with exacerbations of asthma other than life threatening.[786] 1++

A **Use high-dose inhaled β_2 agonists as first line agents in acute asthma and administer as early as possible. Reserve intravenous β_2 agonists for those patients in whom inhaled therapy cannot be used reliably.**

☑ In acute asthma with life threatening features the nebulised route (oxygen-driven) is recommended.

Parenteral β_2 agonists, in addition to inhaled β_2 agonists, may have a role in ventilated patients or those in extremis; however there is limited evidence to support this.

Most cases of acute asthma will respond adequately to bolus nebulisation of β_2 agonists. Continuous nebulisation of β_2 agonists with an appropriate nebuliser may be more effective than bolus nebulisation in relieving acute asthma for patients with a poor response to initial therapy.[425-427] 1+

A **In severe asthma that is poorly responsive to an initial bolus dose of β_2 agonist, consider continuous nebulisation with an appropriate nebuliser.**

Repeat doses of β_2 agonists at 15-30 minute intervals or give continuous nebulisation of salbutamol at 5-10 mg/hour (requires appropriate nebuliser) if there is an inadequate response to initial treatment. Higher bolus doses, eg 10 mg of salbutamol, are unlikely to be more effective.

6.3.3 STEROID THERAPY

Steroids reduce mortality, relapses, subsequent hospital admission and requirement for β_2 agonist therapy. The earlier they are given in the acute attack the better the outcome.[428,429] 1++

A **Give steroids in adequate doses in all cases of acute asthma.**

Steroid tablets are as effective as injected steroids, provided they can be swallowed and retained.[428] Prednisolone 40-50 mg daily or parenteral hydrocortisone 400 mg daily (100 mg six-hourly) are as effective as higher doses.[430] For convenience, steroid tablets may be given as 2 x 25 mg tablets daily rather than 8-10 x 5 mg tablets. Where necessary soluble prednisolone (sodium phosphate) 5 mg tablets are available. In cases where oral treatment may be a problem consider intramuscular methylprednisolone 160 mg as an alternative to a course of oral prednisolone.[787] 1++

2009

☑ Continue prednisolone 40-50 mg daily for at least five days or until recovery.

Following recovery from the acute exacerbation steroids can be stopped abruptly. Doses do not need tapering provided the patient receives inhaled steroids[431,432] (apart from patients on maintenance steroid treatment or rare instances where steroids are required for three or more weeks). 1+

It is not known if inhaled steroids provide further benefit in addition to systemic steroids. Inhaled steroids should however be started, or continued as soon as possible to commence the chronic asthma management plan.[788,789] 1++

2009

6.3.4 IPRATROPIUM BROMIDE

Combining nebulised ipratropium bromide with a nebulised β_2 agonist produces significantly greater bronchodilation than a β_2 agonist alone, leading to a faster recovery and shorter duration of admission. Anticholinergic treatment is not necessary and may not be beneficial in milder exacerbations of asthma or after stabilisation.[434-436] 1++

B **Add nebulised ipratropium bromide** *(0.5 mg 4-6 hourly)* **to β_2 agonist treatment for patients with acute severe or life threatening asthma or those with a poor initial response to β_2 agonist therapy.**

6.3.5 MAGNESIUM SULPHATE

2009 There is some evidence that, in adults, magnesium sulphate has bronchodilator effects.[790] Experience suggests that magnesium is safe when given by the IV or nebulised route. Trials comparing these routes of administration are awaited. 1++

2009 Studies report the safe use of nebulised magnesium sulphate, in a dose of 135 mg-1152 mg, in combination with β_2 agonists, with a trend towards benefit in hospital admission.[791,792] A single dose of IV magnesium sulphate is safe and may improve lung function in patients with acute severe asthma.[437] 1++

The safety and efficacy of repeated IV doses have not been assessed. Repeated doses could cause hypermagnesaemia with muscle weakness and respiratory failure. 1++

B **Consider giving a single dose of IV magnesium sulphate for patients with:**

- **acute severe asthma who have not had a good initial response to inhaled bronchodilator therapy**
- **life threatening or near fatal asthma.**

☑ IV magnesium sulphate (1.2-2 g IV infusion over 20 minutes) should only be used following consultation with senior medical staff.

2009 More studies are needed to determine the optimal route, frequency and dose of magnesium sulphate therapy.

6.3.6 INTRAVENOUS AMINOPHYLLINE

In acute asthma, IV aminophylline is not likely to result in any additional bronchodilation compared to standard care with inhaled bronchodilators and steroids. Side effects such as arrhythmias and vomiting are increased if IV aminophylline is used.[438] 1++

☑ Use IV aminophylline only after consultation with senior medical staff.

Some patients with near-fatal asthma or life threatening asthma with a poor response to initial therapy may gain additional benefit from IV aminophylline (5 mg/kg loading dose over 20 minutes unless on maintenance oral therapy, then infusion of 0.5-0.7 mg/kg/hr). Such patients are probably rare and could not be identified in a meta-analysis of trials.[438] If IV aminophylline is given to patients on oral aminophylline or theophylline, blood levels should be checked on admission. Levels should be checked daily for all patients on aminophylline infusions.

6.3.7 LEUKOTRIENE RECEPTOR ANTAGONISTS

There is insufficient evidence at present to make a recommendation about the use of leukotriene receptor antagonists in the management of acute asthma.

6.3.8 ANTIBIOTICS

When an infection precipitates an exacerbation of asthma it is likely to be viral. The role of bacterial infection has been overestimated.[439] 1++

B **Routine prescription of antibiotics is not indicated for acute asthma.**

6.3.9 HELIOX

2009

The use of heliox, (helium/oxygen mixture in a ratio of 80:20 or 70:30), either as a driving gas for nebulisers, as a breathing gas, or for artificial ventilation in adults with acute asthma is not supported on the basis of present evidence.[440, 441] A systematic review of ten trials, including 544 patients with acute asthma, found no improvement in pulmonary function or other outcomes in adults treated with heliox, although the possibility of benefit in patients with more severe obstruction exists.[793, 794] Heliox requires the use of specifically designed or modified breathing circuits and ventilators. 1+ 1++

B **Heliox is not recommended for use in acute asthma outside a clinical trial setting.**

6.3.10 INTRAVENOUS FLUIDS

There are no controlled trials, observational or cohort studies of differing fluid regimes in acute asthma. Some patients with acute asthma require rehydration and correction of electrolyte imbalance. Hypokalaemia can be caused or exacerbated by β_2 agonist and/or steroid treatment and must be corrected.

6.3.11 NEBULISED FUROSEMIDE

2009

Although theoretically furosemide may produce bronchodilation, a review of three small trials failed to show any significant benefit of treatment with nebulised furosemide compared to β_2 agonists.[795] 1+

6.3.12 REFERRAL TO INTENSIVE CARE

Indications for admission to intensive care or high-dependency units include patients requiring ventilatory support and those with severe acute or life threatening asthma who are failing to respond to therapy, as evidenced by:

- deteriorating PEF
- persisting or worsening hypoxia
- hypercapnea
- arterial blood gas analysis showing fall in pH or rising H^+ concentration 2+
- exhaustion, feeble respiration
- drowsiness, confusion, altered conscious state
- respiratory arrest.[322,401]

Not all patients admitted to the Intensive Care Unit (ICU) need ventilation, but those with worsening hypoxia or hypercapnea, drowsiness or unconsciousness and those who have had a respiratory arrest require intermittent positive pressure ventilation. Intubation in such patients is very difficult and should ideally be performed by an anaesthetist or ICU consultant. [322,401]

C **All patients transferred to intensive care units should be accompanied by a doctor suitably equipped and skilled to intubate if necessary.**

6.3.13 NON-INVASIVE VENTILATION

Non-invasive ventilation (NIV) is well established in the management of ventilatory failure caused by extrapulmonary restrictive conditions and exacerbations of COPD. Hypercapneic respiratory failure developing during an acute asthmatic episode is an indication for urgent ICU admission. It is unlikely that NIV would replace intubation in these very unstable patients but it has been suggested that this treatment can be used safely and effectively.[442] 4

2009 A Cochrane review found only one trial, with 30 patients, on NIV which showed improvement in hospitalisation rates, discharge from emergency departments and lung function. Larger RCTs are needed to determine the role of NIV in treating patients with acute asthma.[796] 1++

2009 ☑ NIV should only be considered in an ICU or equivalent clinical setting.

6.4 FURTHER INVESTIGATION AND MONITORING

☑
- Measure and record PEF 15-30 minutes after starting treatment, and thereafter according to the response. Measure and record PEF before and after nebulised or inhaled β_2 agonist bronchodilator *(at least four times daily)* throughout the hospital stay and until controlled after discharge.
- Record oxygen saturation by oximetry and maintain arterial SpO_2 at 94-98%.
- Repeat measurements of blood gas tensions within one hour of starting treatment if:
  - the initial PaO_2 is <8 kPa unless SpO_2 is $>92\%$; or
  - the initial $PaCO_2$ is normal or raised; or
  - the patient's condition deteriorates.

2009

☑
- Measure them again if the patient's condition has not improved by 4-6 hours.
- Measure and record the heart rate.
- Measure serum potassium and blood glucose concentrations.
- Measure the serum theophylline concentration if aminophylline is continued for more than 24 hours *(aim at a concentration of 10-20mg/l or 55-110 mol/l)*.

6.5 ASTHMA MANAGEMENT PROTOCOLS AND PROFORMAS

The use of structured proformas facilitates improvements in the process of care in emergency departments and hospital wards and improves patient outcomes. The use of this type of documentation can assist data collection aimed at determining quality of care and outcomes.[409,443,445] 2++

6.6 HOSPITAL DISCHARGE AND FOLLOW UP *(see annex 4)*

6.6.1 TIMING OF DISCHARGE

No single physiological parameter defines absolutely the timing of discharge from an admission with acute asthma. Patients should have clinical signs compatible with home management, be on reducing amounts of β_2 agonist (preferably no more than four hourly) and be on medical therapy they can continue safely at home.

Although diurnal variability of PEF is not always present during an exacerbation, evidence suggests that patients discharged with PEF $<75\%$ best or predicted and with diurnal variability $>25\%$ are at greater risk of early relapse and readmission.[446,447] 2+

6.6.2 PATIENT EDUCATION

Following discharge from hospital or emergency departments, a proportion of patients re-attend with more than 15% re-attending within two weeks. Some repeat attenders need emergency care, but many delay seeking help, and are under-treated and/or under-monitored.[448] 2+

Prior to discharge, trained staff should give asthma education. This should include education on inhaler technique and PEF record keeping, with a written PEF and symptom-based action plan being provided allowing the patient to adjust their therapy within recommendations. These measures have been shown to reduce morbidity after the exacerbation and reduce relapse rates.[449] 1++

2009 There is some experience of a discrete population of patients who use emergency departments rather than primary care services for their asthma care.[90] Education has been shown to reduce subsequent hospital admission and improve attendance at scheduled appointments and self management techniques but does not improve re-attendance at emergency departments.[797] 1++

For the above groups there is a role for a trained asthma liaison nurse based in, or associated with, the emergency department.[797]

See also section 9

6.6.3 FOLLOW UP

A careful history should elicit the reasons for the exacerbation and explore possible actions the patient should take to prevent future emergency presentations.

Medication should be altered depending upon the assessment and the patient provided with an asthma action plan aimed at preventing relapse, optimising treatment and preventing delay in seeking assistance in the future.

Follow up should be arranged prior to discharge with the patient's general practitioner or asthma nurse within two working days; and with a hospital specialist asthma nurse or respiratory physician at about one month after admission.

2009 In a small RCT follow-up care by a nurse specialist was as effective and safe as that given by a respiratory doctor.[798] 1+

2009 Assisting patients in making appointments while being treated for acute asthma in emergency departments may improve subsequent attendance at primary care centres.[799] 1+

☑ It is essential that the patient's primary care practice is informed within 24 hours of discharge from the emergency department or hospital following an asthma exacerbation. Ideally this communication should be directly with a named individual responsible for asthma care within the practice, by means of fax or email.

6.7 ACUTE ASTHMA IN CHILDREN AGED OVER 2 YEARS

6.7.1 CLINICAL ASSESSMENT

Table 12 details criteria for assessment of severity of acute asthma attacks in children. *See also annexes 5-7.*

2009 *Table 12: Clinical features for assessment of severity*[800]

Life threatening asthma	Any one of the following in a child with severe asthma:	
	Clinical signs	Measurements
	Silent chest	SpO_2 < 92%
	Cyanosis	PEF < 33% best or predicted
	Poor respiratory effort	
	Hypotension	
	Exhaustion	
	Confusion	
Acute severe asthma	Can't complete sentences in one breath or too breathless to talk or feed SpO_2 < 92% PEF 33-50% best or predicted Pulse > 140 in children aged 2-5 years > 125 in children aged > 5 years Respiration > 40 breaths/min aged 2-5 years > 30 breaths/min aged 7-5 years	
Moderate asthma exacerbation	Able to talk in sentences SpO_2 ≥ 92% PEF ≥ 50% best or predicted Heart rate ≤140/min in children aged 2-5 years ≤125/min in children > 5 years Respiratory rate ≤ 40/min in children aged 2-5 years ≤ 30/min in children > 5 years	

Before children can receive appropriate treatment for acute asthma in any setting, it is essential to assess accurately the severity of their symptoms. The following clinical signs should be recorded:

- Pulserate
  (increasing tachycardia generally denotes worsening asthma; a fall in heart rate in life threatening asthma is a pre-terminal event)
- Respiratory rate and degree of breathlessness
  (ie too breathless to complete sentences in one breath or to feed)
- Use of accessory muscles of respiration
  (best noted by palpation of neck muscles)
- Amount of wheezing
  (which might become biphasic or less apparent with increasing airways obstruction)
- Degree of agitation and conscious level
  (always give calm reassurance).

Clinical signs correlate poorly with the severity of airways obstruction.[450-453] Some children with acute severe asthma do not appear distressed. | 2++

☑ Decisions about admission should be made by trained clinicians after repeated assessment of the response to bronchodilator treatment.

6.7.2 PULSE OXIMETRY

2009 Accurate measurements of oxygen saturation are essential in the assessment of all children with acute wheezing. Oxygen saturation monitors should be available for use by all health professionals assessing acute asthma in both primary and secondary care settings.

Low oxygen saturations after initial bronchodilator treatment selects a more severe group of patients.[450,453] 2++

B **Consider intensive inpatient treatment for children with SpO_2 < 92% in air after initial bronchodilator treatment.**

6.7.3 PEF

2009 PEF measurements can be of benefit in assessing children who are familiar with the use of such devices. The best of three PEF measurements, ideally expressed as a percentage of personal best, can be useful in assessing the response to treatment.

A measurement of < 50% predicted PEF or FEV_1 with poor improvement after initial bronchodilator treatment is predictive of a more prolonged asthma attack.

6.7.4 CHEST X-RAY

Chest X-rays rarely provide additional useful information and are not routinely indicated.[454,455]

2009 ☑ A chest X-ray should be performed if there is subcutaneous emphysema, persisting unilateral signs suggesting pneumothorax, lobar collapse or consolidation and/or life threatening asthma not responding to treatment.

6.7.5 BLOOD GASES

2009 Blood gas measurements should be considered if there are life threatening features not responding to treatment. Arteriolised ear lobe blood gases can be used to obtain an accurate measure of pH and pCO_2.[783] If ear lobe sampling is not practicable a finger prick sample can be an alternative. Normal or raised pCO_2 levels are indicative of worsening asthma. A more easily obtained free flowing venous blood pCO_2 measurement of < 6kPA (45mm Hg) excludes hypercapnia.[783] 4

6.8 INITIAL TREATMENT OF ACUTE ASTHMA IN CHILDREN AGED OVER 2 YEARS

2009 There is good evidence supporting recommendations for the initial treatment of acute asthma presenting to primary and secondary healthcare resources. There is less evidence to guide the use of second line therapies to treat the small number of severe cases poorly responsive to first line measures. Despite this, the risks of death and other adverse outcomes after admission to hospital are extremely small irrespective of the treatment options chosen.

2009 ☑ β_2 agonists should be given as first line treatment. Increase β_2 agonist dose by two puffs every two minutes according to response up to ten puffs.

2009 ☑ Children with acute asthma at home and symptoms not controlled by up to 10 puffs of salbutamol via pMDI and spacer, or 2.5-5 mg of nebulised salbutamol, should seek urgent medical attention. Additional doses of bronchodilator should be given as needed whilst awaiting medical attention if symptoms are severe.

2009 ☑ Paramedics attending to children with acute asthma should administer nebulised salbutamol driven by oxygen if symptoms are severe whilst transferring the child to the emergency department.

2009 ☑ Children with severe or life threatening asthma should be transferred to hospital urgently.

Emergency units attending to children with acute asthma should have a registered sick children's nurse available on duty at all times and staff familiar with the specific needs of children. Using a proforma can increase the accuracy of severity assessment.

2009 The use of an assessment-driven algorithm and an integrated care pathway has been shown to reduce hospital stay without substantial increases in treatment costs.[801]

D **The use of structured care protocols detailing bronchodilator usage, clinical assessment, and specific criteria for safe discharge is recommended.**

6.8.1 OXYGEN

☑ Children with life threatening asthma or SpO_2 <94% should receive high flow oxygen via a tight fitting face mask or nasal cannula at sufficient flow rates to achieve normal saturations.

6.8.2 INHALED β_2 AGONISTS (SALBUTAMOL/TERBUTALINE)

A **Inhaled β_2 agonists are the first line treatment for acute asthma.[457-460]**

Assessment of response should be based on accurately recorded clinical observations and repeat measurements of oxygenation (SpO_2). Children receiving β_2 agonists via pMDI + spacer are less likely to have tachycardia and hypoxia than when the same drug is given via a nebuliser.[353] 1+

A **pMDI + spacer is the preferred option in mild to moderate asthma.**

Children aged <3 years are likely to require a face mask connected to the mouthpiece of a spacer for successful drug delivery. Inhalers should be actuated into the spacer in individual puffs and inhaled immediately by tidal breathing (for five breaths).

Frequent doses of β_2 agonists are safe for the treatment of acute asthma,[457-459] although children with mild symptoms benefit from lower doses.[460] 1+

B **Individualise drug dosing according to severity and adjust according to the patient's response.**

2009 Two to four puffs of a salbutamol 100 mcg repeated every 10-20 minutes according to clinical response might be sufficient for mild attacks although up to 10 puffs might be needed for more severe asthma. Single puffs should be given one at a time and inhaled separately with five tidal breaths. If hourly doses of bronchodilators are needed for more than 4-6 hours, the patient should be switched to nebulised bronchodilators.

2009 Children with severe or life threatening asthma (SpO_2 <92%) should receive frequent doses of nebulised bronchodilators driven by oxygen (2.5-5 mg salbutamol or 5-10 mg terbutaline).

2009 Doses can be repeated every 20-30 minutes. Continuous nebulised β_2 agonists are of no greater benefit than the use of frequent intermittent doses in the same total hourly dosage.[463,464] If there is poor response to the initial dose of β_2 agonists, subsequent doses should be given in combination with nebulised ipratropium bromide.

2009 ☑ Discontinue long-acting β_2 agonists when short-acting β_2 agonists are required more often than four-hourly.

6.8.3 IPRATROPIUM BROMIDE

2009 There is good evidence for the safety and efficacy of frequent doses of ipratropium bromide (every 20-30 minutes) used in addition to β_2 agonists for the first two hours of a severe asthma attack. Benefits are more apparent in the most severe patients.[471] 1+

A **If symptoms are refractory to initial β_2 agonist treatment, add ipratropium bromide** *(250 mcg/dose mixed with the nebulised β_2 agonist solution).*

2009 Frequent doses up to every 20-30 minutes (250 mcg/dose mixed with 5 mg of salbutamol solution in the same nebuliser) should be used for the first few hours of admission. Salbutamol dose should be weaned to one-to two-hourly thereafter according to clinical response. The ipratropium dose should be weaned to four-to-six-hourly or discontinued. Once improving on two- to four-hourly salbutamol, patients should be switched to pMDI and spacer treatment as tolerated.

☑ Repeated doses of ipratropium bromide should be given early to treat children who are poorly responsive to β_2 agonists.

6.8.4 STEROID THERAPY

Steroid tablets

2009 The early use of steroids in emergency departments and assessment units can reduce the need for hospital admission and prevent a relapse in symptoms after initial presentation.[428, 429] Benefits can be apparent within three to four hours.

A **Give prednisolone early in the treatment of acute asthma attacks.**

A soluble preparation dissolved in a spoonful of water is preferable in those unable to swallow tablets. Use a dose of 20 mg for children 2-5 years old and 30-40 mg for children >5 years.

Oral and intravenous steroids are of similar efficacy.[430,465,466] Intravenous hydrocortisone (4 mg/kg repeated four-hourly) should be reserved for severely affected children who are unable to retain oral medication. 1+

Larger doses do not appear to offer a therapeutic advantage for the majority of children.[467] There is no need to taper the dose of steroid tablets at the end of treatment. 2+

☑ Use a dose of 20 mg prednisolone for children aged 2-5 years and a dose of 30-40 mg for children >5 years. Those already receiving maintenance steroid tablets should receive 2 mg/kg prednisolone up to a maximum dose of 60 mg.

- Repeat the dose of prednisolone in children who vomit and consider intravenous steroids in those who are unable to retain orally ingested medication.
- Treatment for up to three days is usually sufficient, but the length of course should be tailored to the number of days necessary to bring about recovery. Weaning is unnecessary unless the course of steroids exceeds 14 days.[431,432]

Inhaled steroids

There is insufficient evidence to support the use of inhaled steroids as alternative or additional treatment to steroid tablets for acute asthma.[433,468-470]

☑ Do not initiate inhaled steroids in preference to steroid tablets to treat children with acute asthma.

Children with chronic asthma not receiving regular preventative treatment will benefit from initiating inhaled steroids as part of their long term management. There is no evidence that increasing the dose of inhaled steroids is effective in treating acute symptoms, but it is good practice for children already receiving inhaled steroids to continue with their usual maintenance doses.

6.8.5 LEUKOTRIENE RECEPTOR ANTAGONISTS

2009 Initiating oral montelukast in primary care settings, early after the onset of acute asthma symptoms, can result in decreased asthma symptoms and the need for subsequent healthcare attendances in those with mild exacerbations.[777, 802] There is no clear evidence to support the use of leukotriene receptor antagonists for moderate to severe acute asthma.[803] 1+

6.9 SECOND LINE TREATMENT OF ACUTE ASTHMA IN CHILDREN AGED OVER 2 YEARS

2009 Children with continuing severe asthma despite frequent nebulised β_2 agonists and ipratropium bromide plus oral steroids, and those with life threatening features, need urgent review by a specialist with a view to transfer to a high dependency unit or paediatric intensive care unit (PICU) to receive second line intravenous therapies. There are three options to consider; salbutamol, aminophylline and magnesium sulphate.

6.9.1 IV SALBUTAMOL

The role of intravenous β_2 agonists in addition to nebulised treatment remains unclear.[424] One study has shown that an IV bolus of salbutamol given in addition to near-maximal doses of nebulised salbutamol results in clinically significant benefits for those with moderate to severe asthma.[424] 1+

B **Consider early addition of a single bolus dose of intravenous salbutamol** *(15 mcg/kg over 10 minutes)* ***in*** **severe cases where the patient has not responded to initial inhaled therapy.**

2009 A continuous intravenous infusion of salbutamol should be considered when there is uncertainty about reliable inhalation or for severe refractory asthma. This should be given in a high dependency unit with continuous ECG monitoring and twice daily electrolyte monitoring. Doses above 1-2 mcg/kg/min (200 mcg/ml solution) should be given in a PICU setting (up to 5 mcg/kg/min). Nebulised bronchodilators should be continued while the patient is receiving intravenous bronchodilators. Once the patient is improving the intravenous infusion should be reduced before reducing the frequency of nebulised bronchodilators.

2009 ☑ When inserting an IV cannula take a blood sample to measure serum electrolytes. Serum potassium levels are often low after multiple doses of β_2 agonists and should be replaced.

6.9.2 IV AMINOPHYLLINE

2009 There is no evidence that aminophylline is of benefit for mild to moderate asthma and side effects are common and troublesome.[438, 472] One well conducted study has shown evidence of benefit in severe acute asthma unresponsive to multiple doses of β_2 agonists and steroids, although the loading dose used was double that currently recommended in the UK and a third of patients were withdrawn from active medication because of vomiting.[473] Two studies have compared intravenous β_2 agonists with intravenous theophylline/aminophylline. One demonstrated equivalence.[804] The other resulted in a shorter period of inpatient treatment among the children receiving an aminophylline bolus followed by infusion but in the salbutamol arm of the study an infusion was not given after the bolus dose.[805] 1+ 2+

A **Aminophylline is not recommended in children with mild to moderate acute asthma.**

2009 C **Consider aminophylline in a HDU or PICU setting for children with severe or life threatening bronchospasm unresponsive to maximal doses of bronchodilators plus steroids.**

A 5 mg/kg loading dose should be given over 20 minutes with ECG monitoring (omit in those receiving maintenance oral theophyllines) followed by a continuous infusion at 1 mg/kg/hour. Measure serum theophylline levels in patients already receiving oral treatment and in those receiving prolonged treatment.

6.9.3 IV MAGNESIUM SULPHATE

Intravenous magnesium sulphate is a safe treatment for acute asthma although its place in management is not yet established.[437,475] Doses of up to 40 mg/kg/day (maximum 2 g) by slow infusion have been used. Studies of efficacy for severe childhood asthma unresponsive to more conventional therapies have been inconsistent in providing evidence of benefit. 1+

6.9.4 OTHER THERAPIES

There is no evidence to support the use of heliox, DNase or mucolytics for the treatment of acute asthma in childhood. Nebulised magnesium sulphate is being evaluated as a treatment for acute asthma but is not yet recommended.

There is insufficient evidence to support or refute the role of antibiotics in acute asthma,[305] but the majority of acute asthma attacks are triggered by viral infection.

☑ Do not give antibiotics routinely in the management of children with acute asthma.

6.9.5 DISCHARGE PLANNING

Children can be discharged when stable on 3-4 hourly inhaled bronchodilators that can be continued at home.[476] PEF and/or FEV_1 should be >75% of best or predicted and SpO_2 >94%.

Adult studies show that "optimal care" comprising self monitoring, regular review and a written asthma action plan can improve outcomes.[407] Acute asthma attacks should be considered a failure of preventive therapy and thought should be given about how to help families avoid further severe episodes.

Discharge plans should address the following:

- check inhaler technique
- consider the need for preventer treatment
- 2009 provide a written asthma action plan for subsequent asthma exacerbations with clear instructions about the use of bronchodilators and the need to seek urgent medical attention in the event of worsening symptoms not controlled by up to 10 puffs of salbutamol 4 hourly
- arrange follow up by primary care services within 48 hours
- arrange follow up in a paediatric asthma clinic within one to two months
- 2009 arrange referral to a paediatric respiratory specialist if there have been life threatening features.

6.10 ASSESSMENT OF ACUTE ASTHMA IN CHILDREN AGED LESS THAN 2 YEARS

The assessment of acute asthma in early childhood can be difficult *(see Annex 8)*. Intermittent wheezing attacks are usually due to viral infection and the response to asthma medication is inconsistent. Prematurity and low birth weight are risk factors for recurrent wheezing. The differential diagnosis of symptoms includes aspiration pneumonitis, pneumonia, bronchiolitis, tracheomalacia, and complications of underlying conditions such as congenital anomalies and cystic fibrosis. These guidelines are intended for those who are thought to have asthma causing acute wheeze. They should not be used as a guide for treating acute bronchiolitis (see SIGN 91: Bronchiolitis in children).[806]

6.11 TREATMENT OF ACUTE ASTHMA IN CHILDREN AGED LESS THAN 2 YEARS

6.11.1 β_2 AGONIST BRONCHODILATORS

A trial of bronchodilator therapy should be considered when symptoms are of concern. If inhalers have been successfully administered but there is no response, review the diagnosis and consider the use of other treatment options.

Inhaled β_2 agonists are the initial treatment of choice for acute asthma. Close fitting face masks are essential for optimal drug delivery. The dose received is increased if the child is breathing appropriately and not taking large gasps because of distress and screaming.

There is good evidence that pMDI + spacer is as effective as, if not better than, nebulisers for treating mild to moderate asthma in children aged ≤ 2 years.[355,478,479] | 1^+

A **For mild to moderate acute asthma, a pMDI + spacer is the optimal drug delivery device.**

Whilst β_2 agonists offer marginal benefits to children aged < 2 years with acute wheeze, there is little evidence for an impact on the need for hospital admission or length of hospital stay.[480-482] | 1^+

Oral β_2 agonists have not been shown to affect symptom score or length of hospital stay for acute asthma in infancy when compared to placebo.[477] | 1^+

B **Oral β_2 agonists are not recommended for acute asthma in infants.**

6.11.2 STEROID THERAPY

Steroid tablets in conjunction with β_2 agonists have been shown to reduce hospital admission rates when used in the emergency department.[483] Steroid tablets have also been shown to reduce the length of hospital stay.[477,480,483] | 1^+

B **Consider steroid tablets in infants early in the management of severe episodes of acute asthma in the hospital setting.**

One study has shown similar benefits when comparing oral and nebulised steroids for acute asthma.[480]

☑ Steroid tablet therapy *(10 mg of soluble prednisolone for up to three days)* is the preferred steroid preparation for use in this age group.

6.11.3 IPRATROPIUM BROMIDE

The addition of ipratropium bromide to β_2 agonists for acute severe asthma may lead to some improvement in clinical symptoms and reduce the need for more intensive treatment. It does not reduce the length of hospital stay either in combination with β_2 agonists or in comparison with placebo.[484] | 1^+

B **Consider inhaled ipratropium bromide in combination with an inhaled β_2 agonist for more severe symptoms.**

6.11.4 FURTHER INVESTIGATION AND MONITORING

Many children with recurrent episodes of viral-induced wheezing in infancy do not go on to have chronic atopic asthma. The majority do not require treatment with regular inhaled steroids. Parents should be advised about the relationship between cigarette smoke exposure and wheezy illnesses *(see sections 3.1.9 and 3.3.1)*. Referral to suitable agencies should be offered to those who wish to give up smoking.

Parents of wheezy infants should receive appropriate discharge plans along similar lines to those given for older children *(see section 6.9.5)*.

7 Special situations

7.1 DIFFICULT ASTHMA

7.1.1 DEFINING AND ASSESSING DIFFICULT ASTHMA

The term difficult asthma generally refers to a clinical situation where a prior diagnosis of asthma exists, and asthma-like symptoms and exacerbations persist, despite prescription of high-dose asthma therapy. There is no universally agreed definition of difficult asthma in children or adults, and specifically at what level of treatment prescription or exacerbation frequency, the term difficult asthma should apply. Consequently there are no precise data on the prevalence of this clinical problem. Previous consensus studies have suggested failure to achieve symptom control despite prescribed high-dose inhaled steroid as a minimum requirement, whilst more recent consensus work has stipulated a treatment level equivalent to at least step 4 *(see section 4.4 and Figures 4, 5 and 6)*, before labelling as "difficult".[485,486]

In this guideline difficult asthma is defined as persistent symptoms and/or frequent exacerbations despite treatment at step 4 or step 5.

Observational uncontrolled studies in subjects with difficult asthma, using multidisciplinary assessment models have identified high rates of alternative or coexistent diagnoses and psychological comorbidity.[29,487-489] These uncontrolled studies, using systematic multidisciplinary assessment and management, have suggested improved outcomes in adults and children, but controlled clinical trials are required. Within this broadly defined group of subjects with difficult asthma, a proportion will have refractory disease, which is relatively resistant to currently available therapies. This group can only be identified after detailed evaluation, including exclusion of alternative causes of persistent symptoms, management of other comorbidities and confirmation of adherence with therapy. 3

D **Patients with difficult asthma should be systematically evaluated, including:**

- **confirmation of the diagnosis of asthma and**
- **identification of the mechanism of persisting symptoms and assessment of adherence with therapy.**

D **This assessment should be facilitated through a dedicated multidisciplinary difficult asthma service, by a team experienced in the assessment and management of difficult asthma.**

7.2 FACTORS CONTRIBUTING TO DIFFICULT ASTHMA

7.2.1 POOR ADHERENCE

Poor adherence with asthma medication is associated with poor asthma outcome in adults and children *(see section 9.2)*. Few studies have addressed this issue in subjects defined as having difficult asthma. In a case control series, poor adherence based on prescription records was identified in 22% of children with difficult to control asthma, though adherence was not reported in the stable controls.[490] In a descriptive study of 100 adult subjects, with a physician diagnosis of 'severe asthma' 28 patients were on >15 mg prednisolone and of these nine (32%) were found to be non-adherent with prednisolone.[488] There is no published evidence that poor adherence, if identified, can be successfully addressed in this population. 2+ 3

C **Poor adherence with maintenance therapy should be considered as a possible mechanism in difficult asthma.**

7.2.2 PSYCHOSOCIAL FACTORS

Fatal and near-fatal asthma have been associated with psychosocial dysfunction *(see section 6.1.3)*. Most observational studies[29, 488, 491-494] and a case control study[495] in subjects with difficult asthma have also suggested a high level of psychological morbidity, though this observation has not been universal.[496,497] 3 2+

A meta-analysis of behavioural adjustment in children suggested increasing 'asthma severity', defined on the basis of treatment requirements was associated with greater behavioural difficulties.[498] The core issue of 'cause and effect' remains unclear; specifically the extent to which persistent asthma symptoms despite aggressive treatment results in psychological morbidity or whether pre-existing psychological morbidity makes asthma difficult to control. 2++

There is a lack of evidence that interventions specifically targeting psychological morbidity in difficult asthma are of benefit. A small proof of concept study targeting depression demonstrated a reduction in oral steroid use[499] and an observational study in 'high-risk' children with asthma suggested potential benefit from joint consultation with a child psychiatrist with an improvement in symptom scores and adherence with therapy.[500] However, a non-blinded randomised intervention study in adults with difficult asthma showed no benefit from a six month nurse-delivered psychoeducational programme.[501] A meta-analysis of psychoeducational interventions in difficult asthma concluded that many of the studies were of poor quality, though there was some evidence of positive effect of psychosocial educational interventions on hospital admissions in adults and children and on symptoms in children. There was not enough evidence to warrant significant changes in clinical practice and little information available on cost effectiveness.[502] 1+ 3

C **Healthcare professionals should be aware that difficult asthma is commonly associated with coexistent psychological morbidity.**

D **Assessment of coexistent psychological morbidity should be performed as part of a difficult asthma assessment. In children this may include a psychosocial assessment of the family.**

7.2.3 DYSFUNCTIONAL BREATHING

Observational uncontrolled studies in subjects with difficult asthma have identified high rates of dysfunctional breathing as an alternative or concomitant diagnosis to asthma causing symptoms.[29,488] It remains unclear what is the best mechanism of identifying and managing this problem. 3

D **Dysfunctional breathing should be considered as part of a difficult asthma assessment.**

7.2.4 ALLERGY

Acute asthma has been associated with IgE dependent sensitisation to indoor allergens.[503] In case control studies, mould sensitisation has been associated with recurrent admission to hospital and oral steroid use[504, 505] and with intensive care unit admissions and respiratory arrest.[506,507] There is no published evidence of any intervention study in this group. Research in this area is required. 2++ 3

C **In patients with difficult asthma and recurrent hospital admission, allergen testing to moulds should be performed.**

7.2.5 MONITORING AIRWAY RESPONSE

Two randomised blinded controlled trials and one open randomised study have supported the use of titrating steroid treatment against sputum eosinophilia in adults with moderate to severe asthma, with greatest benefit seen in patients receiving higher doses of inhaled steroid therapy.[84,86,508] In the study with the largest numbers of patients receiving high dose inhaled steroid treatment, patients who were considered to be poorly adherent with treatment, or had inadequately controlled aggravating factors, such as rhinitis or gastro-oesophageal reflux were specifically excluded.[84] Case series have suggested that sputum induction is safe in patients with difficult to control asthma.[57,509-512] 1+ 1- 3

Controlled studies using FE_{NO} to target treatment have not specifically targeted adults or children with difficult asthma.[85,513,514] 1+

B **In patients with difficult asthma, consider monitoring induced sputum eosinophil counts to guide steroid treatment.**

Revised 2009

7.3 ASTHMA IN PREGNANCY

7.3.1 NATURAL HISTORY AND MANAGEMENT OF STABLE ASTHMA

The majority of women with asthma have normal pregnancies and the risk of complications is small in those with well controlled asthma. Several physiological changes occur during pregnancy that could worsen or improve asthma, but it is not clear which, if any, are important in determining the course of asthma during pregnancy. Pregnancy can affect the course of asthma and asthma and its treatment can affect pregnancy outcomes.

Course of asthma in pregnancy

The natural history of asthma during pregnancy is extremely variable. In a prospective cohort study of 366 pregnancies in 330 women with asthma, the asthma worsened during pregnancy in 35%.[515] 2009 A more recent prospective cohort study of 1,739 pregnant women showed an overall improvement in 23% and deterioration in 30.3%.[807] The conclusions of a meta-analysis of 14 studies is in agreement with the commonly quoted generalisation that during pregnancy about one third of asthma patients experience an improvement in their asthma, one third experience a worsening of symptoms, and one third remain the same.[518] 2009 There is also some evidence that the course of asthma is similar in successive pregnancies.[515,808] A systematic review showed no effect of pregnancy or stage of pregnancy on FEV_1.[809] 1+ 2+

Studies suggest that 11-18% of pregnant women with asthma will have at least one emergency department visit for acute asthma and of these 62% will require hospitalisation.[516,517] Severe asthma is more likely to worsen during pregnancy than mild asthma,[515] but some patients with very severe asthma may experience improvement, whilst symptoms may deteriorate in some patients with mild asthma. 2009 In a large US study, the rates of asthma exacerbation were 13%, 26% and 52% in those with mild, moderate and severe asthma respectively.[807] The corresponding rates of hospitalisation were 2%, 7% and 27%. 2- 2+

2009 A systematic review concluded that, if symptoms do worsen, this is most likely in the second and third trimesters, with the peak in the sixth month.[808] In a large cohort study, the most severe symptoms were experienced by patients between the 24th and 36th week of pregnancy. Thereafter symptoms decreased significantly in the last four weeks and 90% had no asthma symptoms during labour or delivery. Of those who did, only two patients required anything more than inhaled bronchodilators.[515] A further study has confirmed the observation that the last month of pregnancy is the one in which patients are least likely to have an asthma exacerbation.[519] 2+

Effect of asthma on pregnancy

A systematic review has shown that baseline asthma severity does determine what happens to the course of asthma in pregnancy and asthma may affect the risk of adverse outcomes.[521] A cohort study comparing 198 pregnant women with asthma to 198 women without asthma reported that non-atopic patients with asthma tend to have more severe asthma. Pre-eclampsia was also more common in this group. However with adequate surveillance and treatment, pregnancy and delivery complications can be avoided.[520] 2++ 2+

Uncontrolled asthma is associated with many maternal and fetal complications, including hyperemesis, hypertension, pre-eclampsia, vaginal haemorrhage, complicated labour, fetal growth restriction, pre-term birth, increased perinatal mortality, and neonatal hypoxia.[522-525, 807] A large Swedish population based study using record linkage data demonstrated increased risks for pre-term birth, low birth weight, perinatal mortality and pre-eclampsia in women with asthma. The risks for pre-term delivery and low birth weight were higher in women with more severe asthma necessitating admission.[526] 2+

2009 A large prospective cohort study comparing women with moderate and severe asthma with women without asthma found the only significant difference was an increased Caesarean section rate (OR 1.4, 95% CI, 1.1 to 1.8).[807] Logistic regression analysis of the severe group showed an increased risk of gestational diabetes (AOR 3 (95% CI, 1.2 to 7.8)) and pre-term delivery < 37 weeks (AOR 2.2 95% CI, 1.2 to 4.2) but this could have been an effect of corticosteroids. In the Yale asthma study no effect of asthma symptoms or severity was seen on pre-term delivery but oral steroids increased the rate of pre-term delivery and reduced gestation by 2.2 weeks (AOR 1.05 95% CI, 1.01 to1.09).[810] Daily asthma symptoms were associated with an increased risk of fetal growth restriction (AOR 2.25 95% CI, 1.25 to 4.06) and there was a 24% increase with each increased symptom step. This is supported by a systematic review of four studies that concluded asthma exacerbation in pregnancy increases the risk of low birth weight.[811] The RR was 2.54 (95% CI, 1.52 to 4.25) compared to women without asthma. In a large cohort study of 2,123 women with asthma, there was an association of both mean FEV_1 and mean FEV_1 < 80% predicted with gestational hypertension, pre-term delivery < 37 weeks, < 32 weeks and low birth weight.[812] 2+ 2++

In contrast, if asthma is well controlled throughout pregnancy there is little or no increased risk of adverse maternal or fetal complications.[515,516] Pregnancy should therefore be an indication to optimise therapy and maximise lung function in order to reduce the risk of acute exacerbation. 2+

2009 **C** **Monitor pregnant women with moderate/severe asthma closely to keep their asthma well controlled.**

2009 **B** **Women should be advised of the importance of maintaining good control of their asthma during pregnancy to avoid problems for both mother and baby.**

☑ Advise women who smoke about the dangers for themselves and their babies and give appropriate support to stop smoking.

7.4 MANAGEMENT OF ACUTE ASTHMA IN PREGNANCY

The management of acute asthma in pregnancy may be affected by concerns about harmful effects of medication on the fetus. In a prospective controlled study of 51 pregnant women and 500 non-pregnant women presenting with acute asthma to an emergency department in Boston, USA, pregnant patients with asthma were less likely to receive appropriate treatment with steroids and, as a result, were more likely to experience ongoing exacerbation at two weeks.[527] Available studies give little cause for concern regarding treatment side effects *(see section 7.3)* and the maternal and fetal risks of uncontrolled asthma are much greater than the risks from using conventional asthma medications for management of acute asthma. In the last four confidential enquiries into maternal deaths in the UK (covering 1994-2005) there were seventeen deaths from asthma.[528,529 813,814] 2+

2009 Oxygen should be delivered to maintain saturation 94-98% in order to prevent maternal and fetal hypoxia.[783] When interpreting arterial blood gases in pregnancy it should be remembered that the progesterone-driven increase in minute ventilation may lead to relative hypocapnia and a respiratory alkalosis, and higher PaO_2 [815, 816] but oxygen saturations are unaltered.[817] Acidosis is poorly tolerated by the fetus. 4

2009 Drug therapy should be given as for a non-pregnant patient with acute asthma, including nebulised β_2 agonists and early administration of steroid tablets.[515, 517, 519, 522, 523] In severe cases, intravenous β_2 agonists, aminophylline, or intravenous bolus magnesium sulphate can be used as indicated.[818] 2^+

2009 Continuous fetal monitoring should be performed when asthma is uncontrolled or severe, or when fetal assessment on admission is not reassuring. Consideration should be given to early referral to critical care services as impaired ventilatory mechanics in late pregnancy can lower functional residual capacity and may result in earlier oxygen desaturation.[819] Pregnant women may be more difficult to intubate due to anatomical changes especially if they have pre-eclampsia.[820]

2009 C **Give drug therapy for acute asthma as for the non-pregnant patient including systemic steroids and magnesium sulphate.**

2009 D **Deliver high flow oxygen immediately to maintain saturation 94-98%.**

D **Acute severe asthma in pregnancy is an emergency and should be treated vigorously in hospital.**

☑ Continuous fetal monitoring is recommended for severe acute asthma.

2009 ☑ For women with poorly controlled asthma during pregnancy there should be close liaison between the respiratory physician and obstetrician, with early referral to critical care physicians for women with acute severe asthma.

7.5 DRUG THERAPY IN PREGNANCY

2009 In general, the medicines used to treat asthma are safe in pregnancy.[530, 821] A large UK population based case control study found no increased risk of major congenital malformations in children of women receiving asthma treatment in the year before or during pregnancy.[822] The risk of harm to the fetus from severe or chronically under-treated asthma outweighs any small risk from the medications used to control asthma. 2^+

2009 B **Counsel women with asthma regarding the importance and safety of continuing their asthma medications during pregnancy to ensure good asthma control.**

7.5.1 β_2 AGONISTS

2009 No significant association has been demonstrated between major congenital malformations or adverse perinatal outcome and exposure to short-acting β_2 agonists.[530, 531,821-823] A prospective study of 259 pregnant patients with asthma who were using bronchodilators compared with 101 pregnant patients with asthma who were not, and 295 control subjects, found no differences in perinatal mortality, congenital abnormalities, prematurity, mean birth weight, apgar scores or labour/delivery complications.[532] A case control study including 2,460 infants exposed to short-acting β_2 agonists found no increased risk of congenital malformations in exposed infants.[807] 2^+ 3

2009 With regard to long-acting β_2 agonists (LABAs), evidence from prescription event monitoring suggests that salmeterol is safe in pregnancy[533] and although there are some data on formoterol, numbers are small.[824] Systematic review of studies including 190 exposures to LABA demonstrated no increased risk of congenital malformations, pre-term delivery or pre-eclampsia.[825] A case control study including 156 infants exposed to LABA found no increased risk of major congenital malformations.[822] As in other settings, LABAs should be used with an inhaled corticosteroid, ideally as a combination product.[826] 2^+

2009 Data on the use of combination products in pregnancy are scarce although there are no theoretical reasons why these would be more harmful than the same agents given separately. There are some safety data for seretide (salmeterol/fluticasone) but with small numbers.[827]

2009 **B** **Use short acting β_2 agonists as normal during pregnancy.**

2009 **C** **Use long acting β_2 agonists (LABA) as normal during pregnancy.**

7.5.2 INHALED STEROIDS

2009 No significant association has been demonstrated between major congenital malformations or adverse perinatal outcome and exposure to inhaled steroids.[530,534-537, 822, 825, 828] A meta-analysis of four studies of inhaled corticosteroid use in pregnancy showed no increase in the rate of major malformations, pre-term delivery, low birth weight or pregnancy-induced hypertension.[829] The UK case control study included 1,429 infants exposed to inhaled steroids and found no increased risk of major congenital malformations.[822] 2- 2+ 2++

2009 Inhaled anti-inflammatory treatment has been shown to decrease the risk of an acute attack of asthma in pregnancy[519] and the risk of readmission following asthma exacerbation.[517] A randomised placebo controlled trial of inhaled beclometasone versus oral theophylline in moderate asthma in pregnancy showed no difference in the primary outcome of one or more asthma exacerbations resulting in medical intervention, but inhaled beclometasone was better tolerated.[807] 2+

B **Use inhaled steroids as normal during pregnancy.**

7.5.3 THEOPHYLLINES

No significant association has been demonstrated between major congenital malformations or adverse perinatal outcome and exposure to methylxanthines.[530,538] 2+

For women requiring theophylline to maintain asthma control, measurement of theophylline levels is recommended. Since protein binding decreases in pregnancy, resulting in increased free drug levels, a lower therapeutic range is probably appropriate.[539] 4

C **Use oral and intravenous theophyllines as normal during pregnancy.**

D **Check blood levels of theophylline in acute severe asthma and in those critically dependent on therapeutic theophylline levels.**

7.5.4 STEROID TABLETS

2009 There is much published literature showing that steroid tablets are not teratogenic[522, 530, 540] but a slight concern that they may be associated with oral clefts. Data from several studies have failed to demonstrate this association with first trimester exposure to steroid tablets[540, 830] but one case control study found a significant association, although this increase is not significant if only paired controls are considered.[542] Although one meta-analysis reported an increased risk,[541] a prospective study by the same group found no difference in the rate of major birth defects in prednisolone-exposed and control babies.[541] A more recent population based case control study revealed a crude odds ratio of corticosteroid exposure from four weeks before through to 12 weeks after conception of 1.7 (95% CI, 1.1-2.6) for cleft lip.[831] Another case control study[822] including 262 exposed infants found no such association, although this was not limited to first trimester exposure. 2+ 2-

The association is therefore not definite and even if it is real, the benefit to the mother and the fetus of steroids for treating a life threatening disease justify the use of steroids in pregnancy.[524, 815] Moreover, the various studies of steroid exposure include many patients with conditions other than asthma, and the pattern of steroid use was generally as a regular daily dose rather than as short courses, which is how asthma patients would typically receive oral steroids. 2+

Prednisolone is extensively metabolized by placental enzymes so only 10% reaches the fetus, making this the oral steroid of choice to treat maternal asthma in pregnancy. Pregnant women with acute asthma exacerbation are less likely to be treated with steroid tablets than non-pregnant women.[527] Failure to administer steroid tablets when indicated increases the risk of ongoing exacerbation and therefore the risk to the mother and her fetus. 2+

2009 Some studies have found an association between steroid tablet use and pregnancy-induced hypertension or pre-eclampsia, pre-term labour[520] and fetal growth but severe asthma may be a confounding variable.[832] 2+

2009 C **Use steroid tablets as normal when indicated during pregnancy for severe asthma. Steroid tablets should never be withheld because of pregnancy. Women should be advised that the benefits of treatment with oral steroids outweigh the risks.**

7.5.5 LEUKOTRIENE RECEPTOR ANTAGONISTS

2009 Data regarding the safety of leukotriene antagonists (LTRA) in pregnancy are limited. Animal studies and post-marketing surveillance for zafirlukast with 28 pregnancies with 20 exposed in the first trimester and montelukast are reassuring.[833] There are animal data of concern for zileuton.[543] A case control study with 96 cases exposed to LTRAs found no increased risk of major malformations between women with asthma exposed to LTRA and women with asthma taking only beta agonists.[832] A systematic review found no increased risk of malformations or pre-term delivery in nine exposed women.[810, 825] 2- 4 2+ 2++

2009 D **Leukotriene antagonists may be continued in women who have demonstrated significant improvement in asthma control with these agents prior to pregnancy not achievable with other medications.**

7.5.6 CHROMONES

No significant association has been demonstrated between major congenital malformations or adverse perinatal outcome and exposure to chromones.[529, 530,825, 832] 2+

C **Use chromones as normal during pregnancy.**

7.5.7 IMMUNOMODULATION THERAPY

2009 There are as yet no clinical data on the use of omalizumab for moderate-severe allergic asthma in pregnancy. There are some reassuring animal studies re teratogenicity (classed as FDA category B). A registry of pregnancy exposures is being undertaken.

7.6 MANAGEMENT DURING LABOUR

Acute attacks of asthma are very rare in labour, perhaps due to endogenous steroid production. In women receiving steroid tablets there is a theoretical risk of maternal hypothalamic-pituitary-adrenal axis suppression. Women with asthma may safely use all forms of usual labour analgesia.

2009 In some studies there is an association between asthma and an increased Caesarean section rate,[520,544,545] but this may be due to planned Caesarean sections[519] or inductions of labour rather than due to any direct effect of asthma on intrapartum indications. A large prospective cohort study comparing women with moderate and severe asthma with women without asthma found the only significant difference was an increased Caesarean section rate (OR 1.4, 95% CI 1.1-1.8).[807] 2+

Data suggest that the risk of postpartum exacerbation of asthma is increased in women having Caesarean sections.[544] This may relate to the severity of their asthma rather than to the Caesarean section, or to factors such as postoperative pain with diaphragmatic splinting, hypoventilation and atelectasis. Prostaglandin E2 may safely be used for labour inductions.[539] Prostaglandin F2α (carboprost/hemobate®) used to treat postpartum haemorrhage due to uterine atony may cause bronchospasm.[539] Although ergometrine may cause bronchospasm particularly in association with general anaesthesia,[539] this is not a problem encountered when syntometrine (syntocinon/ergometrine) is used for postpartum haemorrhage prophylaxis. 2- 3

Although suppression of the fetal hypothalamic-pituitary-adrenal axis is a theoretical possibility with maternal systemic steroid therapy, there is no evidence from clinical practice or the literature to support this.[546]

☑ Advise women that acute asthma is rare in labour.

☑ Advise women to continue their usual asthma medications in labour.

☑ In the absence of acute severe asthma, reserve Caesarean section for the usual obstetric indications.

C **If anaesthesia is required, regional blockade is preferable to general anaesthesia in women with asthma.**

☑ Women receiving steroid tablets at a dose exceeding prednisolone 7.5 mg per day for more than two weeks prior to delivery should receive parenteral hydrocortisone 100 mg 6-8 hourly during labour.

D **Use prostaglandin F2α with extreme caution in women with asthma because of the risk of inducing bronchoconstriction.**

7.7 DRUG THERAPY IN BREASTFEEDING MOTHERS

The medicines used to treat asthma, including steroid tablets, have been shown in early studies to be safe to use in nursing mothers.[547] There is less experience with newer agents. Less than 1% of the maternal dose of theophylline is excreted into breast milk.[547] 2+

Prednisolone is secreted in breast milk, but milk concentrations of prednisolone are only 5-25% of those in serum.[351] The proportion of an oral or intravenous dose of prednisolone recovered in breast milk is less than 0.1%.[548-550] For maternal doses of at least 20 mg once or twice daily the nursing infant is exposed to minimal amounts of steroid with no clinically significant risk.[548-550] 2+ 3

C **Encourage women with asthma to breastfeed.**

C **Use asthma medications as normal during lactation, in line with manufacturers' recommendations.**

7.8 OCCUPATIONAL ASTHMA

7.8.1 INCIDENCE

The true frequency of occupational asthma is not known, but under-reporting is likely. Published reports, which come from surveillance schemes, compensation registries or epidemiological studies, estimate that occupational asthma may account for about 9-15% of adult onset asthma.[551-553] It is now the commonest industrial lung disease in the developed world with over 400 reported causes.[554-556] 2++

The diagnosis should be suspected in all adults with symptoms of airflow limitation, and positively searched for in those with high-risk occupations or exposures. Patients with pre-existing asthma aggravated non-specifically by dust and fumes at work (work-aggravated asthma) should be distinguished from those with pre-existing asthma who become additionally sensitised to an occupational agent.

B **In patients with adult onset, or reappearance of childhood asthma, clinicians should be suspicious that there may be an occupational cause.**

7.8.2 AT-RISK POPULATIONS

Several hundred agents have been reported to cause occupational asthma and new causes are reported regularly in the medical literature.

The most frequently reported causative agents include isocyanates, flour and grain dust, colophony and fluxes, latex, animals, aldehydes and wood dust.[557-565]

The workers most commonly reported to occupational asthma surveillance schemes include paint sprayers, bakers and pastry makers, nurses, chemical workers, animal handlers, welders, food processing workers and timber workers. [557,558,560,562-568] 2++

Workers reported to be at increased risk of developing asthma include bakers, food processors, forestry workers, chemical workers, plastics and rubber workers, metal workers, welders, textile workers, electrical and electronic production workers, storage workers, farm workers, waiters, cleaners, painters, dental workers and laboratory technicians.[569-572] 2+

7.8.3 DIAGNOSIS

Occupational asthma should be considered in all workers with symptoms of airflow limitation. The best screening question to ask is whether symptoms improve on days away from work. This is more sensitive than asking whether symptoms are worse at work, as many symptoms deteriorate in the hours after work or during sleep.

☑ Adults with airflow obstruction should be asked:

- Are you better on days away from work?
- Are you better on holiday?

Those with positive answers should be investigated for occupational asthma.

These questions are not specific for occupational asthma and also identify those with asthma due to agents at home (who may improve on holidays), and those who do much less physical exertion away from work.[573]

Occupational asthma can be present when tests of lung function are normal, limiting their use as a screening tool. Asthmatic symptoms improving away from work can produce false negative diagnoses, so further validation is needed.

Serial measurement of peak respiratory flow is the most readily available initial investigation, and the sensitivity and specificity of serial peak flow measurement in the diagnosis of occupational asthma are high.[574-580] 3

Although skin prick tests or blood tests for specific IgE are available, there are few standardized allergens commercially available which limits their use. A positive test denotes sensitisation, which can occur with or without disease. The diagnosis of occupational asthma can usually be made without specific bronchial provocation testing, considered to be the gold standard diagnostic test. The availability of centres with expertise and facilities for specific provocation testing is very limited in the UK and the test itself is time consuming.

As a general observation, the history is more useful in excluding occupational asthma than in confirming it. A significant proportion of workers with symptoms that improve on days away from work or on holiday have been shown by objective tests not to have occupational asthma.[581] Expert histories have poor specificity compared with specific challenge testing. Free histories taken by experts have high sensitivity but their specificity is lower.[582-587] 3

D **In suspected work-related asthma, the diagnosis of asthma should be confirmed using standard objective criteria.**

7.8.4 SENSISTIVITY AND SPECIFICITY OF SERIAL PEAK FLOW MEASUREMENTS

Direct and blinded comparisons of serial peak flow measurement with either specific bronchial provocation testing, or an expert diagnosis based on a combination of other types of evidence, reported consistently high sensitivities and specificities, averaging 80% and 90% respectively.[575-578,580,588,589] 3

Just one computed method of analysis has been reported, with a sensitivity of 75% and a specificity of 94%.[97,590] 2^+

Computed analysis of peak flow records has good diagnostic performance, but statistical analysis of serial peak flow measurements appears to be of limited diagnostic value compared to expert interpretation.[578,588,589]

Serial measurements of peak expiratory flow

Measurements should be made every two hours from waking to sleeping for four weeks, keeping treatment constant and documenting times at work.

Minimum standards for diagnostic sensitivity >70% and specificity >85% are:

- At least three days in each consecutive work period
- At least three series of consecutive days at work with three periods away from work (usually about three weeks)
- At least four evenly spaced readings per day.[580]

The analysis is best done with the aid of a criterion-based expert system. Suitable record forms and support are available from www.occupationalasthma.com

D **Objective diagnosis of occupational asthma should be made using serial peak flow measurements, with at least four readings per day.**

7.8.5 NON-SPECIFIC REACTIVITY

Studies of non-specific reactivity are confounded by different methods used, different cut-offs for normality and the interval between last occupational exposure and the performance of the test (increasing time may allow recovery of initial hyper-reactors). Such studies show that non-specific bronchial hyper-reactivity may be normal in 5-40% of specific challenge positive workers. Testing with higher concentrations of methacholine or histamine, at which some people without asthma would react, reduces the number of non-reacting people with occupational asthma, but still leaves some non-reactors. One study showed no additional benefit of non-specific bronchial reactivity measurement over and above a history and specific IgE to inhaled antigens. A normal test of non-specific reactivity is not sufficiently specific to exclude occupational asthma in clinical practice. [576,581,583,586,587,589,591-602] 2^{++}

Changes in non-specific reactivity at and away from work alone have been found to have only moderate sensitivity and specificity for diagnosis. Three studies were identified where at and away from work exposure measurements were attempted. One did not investigate workers further when at work reactivity was normal, limiting its interpretation. Using a 3.2 fold change in reactivity, one study found a sensitivity of 48% and a specificity of 64%. Reducing the required change to twofold increased the sensitivity to 67%, reducing specificity to 54%. A smaller study with 14 workers with occupational asthma showed a sensitivity of 62% and specificity of 78%. [577,589,601] 2-

7.8.6 SPECIFIC BRONCHIAL PROVOCATION TESTING

Specific provocation challenges are usually used as the gold standard for occupational asthma diagnosis making assessments of their diagnostic validity difficult. In addition, there are no standardised methods for many occupational agents. There is also evidence that the threshold exposure increases with time since last exposure, making the tests less sensitive after prolonged absence from work. There are reports of people having non-specific reactions to specific challenges at concentrations likely to be found in the workplace or of negative reactions to specific challenges in workers with otherwise good evidence of occupational asthma when challenge concentrations are confined to levels below occupational exposure standards. [594,597,600,603,604] 4

D **A negative specific bronchial challenge in a worker with otherwise good evidence of occupational asthma is not sufficient to exclude the diagnosis.**

7.9 MANAGEMENT OF OCCUPATIONAL ASTHMA

The aim of management is to identify the cause, remove the worker from exposure, and for the worker to have worthwhile employment.

Complete avoidance of exposure may or may not improve symptoms and bronchial hyperresponsiveness. Both the duration of continued exposure following the onset of symptoms and the severity of asthma at diagnosis may be important determinants of outcome. Early diagnosis and early avoidance of further exposure, either by relocation of the worker or substitution of the hazard offer the best chance of complete recovery. Workers who remain in the same job and continue to be exposed to the same causative agent after diagnosis are unlikely to improve and symptoms may worsen. The likelihood of improvement or resolution of symptoms or of preventing deterioration is greater in workers who have no further exposure to the causative agent. [576,605-613] 2++

Several studies have shown that the prognosis for workers with occupational asthma is worse for those who remain exposed for more than one year after symptoms develop, compared with those removed earlier.[614-616]

D **Relocation away from exposure should occur as soon as diagnosis is confirmed, and ideally within 12 months of the first work-related symptoms of asthma.**

There is consistent evidence from clinical and workforce case series that about one third of workers with occupational asthma are unemployed after diagnosis. It is unclear whether this risk is higher than that for other adults with asthma. [582,617,618] The risk of unemployment may fall with increasing time after diagnosis.[619] There is consistent evidence that loss of employment following a diagnosis of occupational asthma is associated with loss of income. Adults with occupational asthma may find employment more difficult than adults with non-occupational asthma.[617,618] Approximately one third of workers with occupational asthma have been shown to be unemployed up to six years after diagnosis.[582,617-624] 2-

8 Organisation and delivery of care, and audit

8.1 ROUTINE PRIMARY CARE

8.1.1 ACCESS TO ROUTINE PRIMARY CARE

Primary care services delivered by doctors and nurses trained in asthma management improves diagnosis, prescribing, education, monitoring, and continuity of care [625,626] Successful training programmes typically include outreach educational visits to practices or practitioners using interactive educational methods focused around clinical guidelines, occasionally including audit and feedback of care.[625,627,628] 1+

A **All people with asthma should have access to primary care services delivered by doctors and nurses with appropriate training in asthma management.**

❖ *Audit the percentage of clinicians who have taken part in a suitable asthma educational update within last two years.*

8.1.2 STRUCTURED REVIEW

Proactive clinical review of people with asthma improves clinical outcomes. Evidence for benefit is strongest when reviews include discussion and use of a written action plan.[407] Benefits include reduced school or work absence, reduced exacerbation rate, improved symptom control and reduced attendance at the emergency department.[629,630] Proactive structured review, as opposed to opportunistic or unscheduled review, is associated with reduced exacerbation rate and days lost from normal activity.[626,631,632] It is difficult to be prescriptive about the frequency of review as need will vary with the severity of the disease. Outcome is probably similar whether a practice nurse (PN), or a general practitioner (GP) conducts the review. Clinicians trained in asthma management achieve better outcomes for their patients.[626,633,634] 2+ 3 4 1+

A **In primary care, people with asthma should be reviewed regularly by a nurse or doctor with appropriate training in asthma management. Review should incorporate a written action plan.**

❖ *Audit the percentage of patients reviewed annually. Consider focusing on particular groups such as those overusing bronchodilators, patients on higher treatment steps, those with exacerbations or from groups with more complex needs.*

❖ *Audit the percentage of patients receiving action plans. Consider focusing on subgroups listed above.*

READ coding of patients who are newly diagnosed or register at a practice will ensure a meaningful database for audit and review purposes. Specifically identifying patients with high risk asthma (eg those with frequent admissions) in an effort to target more detailed input is logical but supported by limited evidence.[635] Not all patients want regular review, or are willing to attend a pre-arranged appointment. Reviews carried out by telephone may be as effective as those using face-to-face consultations,[636] but face-to-face review will be appropriate for some patients, such as those with poor asthma control or inhaler-related problems. 2++

B **Consider carrying out routine reviews by telephone for people with asthma.**

Asthma clinics in primary care may be a convenient way of delivering care, but there is limited evidence that they themselves improve outcome.[291] Most practices will provide asthma reviews as part of routine appointment sessions. It is what happens during the review consultation that matters.[637-640] Audit that feeds back guidelines recommendations on the management of individual patients may improve outcomes.[641,642]

C **General practices should maintain a register of people with asthma.**

C **Clinical review should be structured and utilise a standard recording system.**

B **Feedback of audit data to clinicians should link guidelines recommendations to management of individual patients.**

The ideal content of an asthma review consultation is uncertain. Discussion and provision of a written action plan leads to improved outcomes.[643] Other activities likely to be important are reviewing understanding of medication role and use, checking inhaler technique, recording lung function. Structured review systems such as the Royal College of Physicians 'Three Key Questions',[109] the Tayside Asthma Stamp,[644] and the modified Jones Morbidity Index[645] improve the recording of relevant data and may prompt a search for causes of suboptimal asthma control, such as under-treatment, poor adherence or poor inhaler technique. However, such tools can lead to a more physician-centred or template-directed consultation. Reviewing patients using a patient-centred style of consultation can lead to improved outcomes.[625]

8.1.3 SHARED CARE

Shared care schemes have been shown to be effective in some healthcare environments. There are no UK studies directly comparing primary and secondary care management, but international work suggests there may be little difference: what is done would appear to be more important than who by or where. [646] 1+ 2+

Integrated care schemes such as Grampian Asthma Study in Integrated Care (GRASSIC) suggest that place of care is not directly linked to clinical outcome.[647-650] Shared care had a similar outcome to outpatient care. Outreach support for primary care by asthma specialist nurses may reduce unscheduled asthma care but only if targeted around follow-up of patients recently attending secondary care with exacerbations. 1+ 2+

Community pharmacists trained in asthma care and teaching self management skills may improve asthma control,[651,652] although evidence is sparse and inconsistent.[653] 1-

8.1.4 PATIENT SUBGROUPS

Ethnic subgroups have adverse clinical outcomes, including higher hospital admission and exacerbation rates.[654,655] In some countries ethnic minority groups have higher death rates due to asthma than do their contemporaries.[656,657] Minority groups describe poorer access to primary care and acute medical care,[658] and compared with majority groups, have a higher use of emergency facilities for routine care.[659] Educating primary care clinicians improves diagnosis, prescribing, education, and continuity of care for minority group children.[659] There is an established link between poor socioeconomic status and adverse asthma outcome.[660-664] 2+ 3 4 1+

Adolescents and the elderly are particularly vulnerable to the adverse effects of asthma. Adolescents and young adults make more frequent use of emergency asthma healthcare services, make less use of structured clinical review services than other age groups, and have high reliance on bronchodilators.[665,666] Asthma in the elderly is a neglected area of research, despite high mortality and morbidity.[391,667,668] 3

D **Healthcare professionals who provide asthma care should have heightened awareness of the complex needs of ethnic minorities, socially disadvantaged groups, adolescents, the elderly and those with communication difficulties.**

❖ *Audit asthma outcomes in relevant subgroups of the population.*

8.2 ACUTE EXACERBATIONS

People with asthma who experience deterioration in symptom control leading to an acute exacerbation can access a wide variety of sources of care. Few studies have looked at the relative merits of one type of service compared to another. Exceptions include a UK study showing a better outcome for patients managed by a specialist respiratory ward compared to a general medical ward, and a US study showing more favourable outcome in patients managed by specialist allergists compared to generalists.[669,670] 2+ 3

C **Manage hospital inpatients with asthma in specialist rather than general units.**

☑ All services involved in the care of acute asthma should be staffed by appropriately trained personnel and have access to all the equipment needed to manage acute asthma.

❖ *Audit the percentage of inpatients receiving care from specialist asthma nurse or chest physician.*

Models of care addressing access such as NHS Direct/NHS 24 produce similar outcomes to routine general practice, but have high referral rates and are unlikely to promote the continuity of care required for longer term management.[671] 3

A structured clinical assessment and a standardised recording system are associated with favourable outcome in acute exacerbations.[672] Audit of the management of patients with acute asthma attacks is associated with improved concordance with recommended guidelines and in turn improved clinical outcome and reduced exacerbation rate.[673-675] 2+ 2- 3

There is no evidence that the publication of guidelines per se improves care: clinicians need to link best practice to the management of individual patients. This effect is apparent in hospital and general practice care.[447] Certain actions, for example early prescription of oral corticosteroids for acute exacerbations of asthma, reduce hospitalisation and relapse rates. Clinicians should refer to relevant chapters in this guideline for advice.

B **Clinicians in primary and secondary care should treat asthma according to recommended guidelines.**

❖ *Audit the percentage of patients treated according to key guideline recommendations.*

Using acute asthma management protocols and clinical pathways can be beneficial and cost effective. Sub-optimal control of asthma leading to exacerbation is more expensive to manage than well controlled asthma.[630] Early discharge schemes from hospital and emergency departments may be cost effective.[445,676] 2+ 3

The safety of telephone help lines has not been established. 'Direct dial' emergency admission schemes may be of benefit to a small group of patients with severe or 'brittle' asthma but there is insufficient evidence to justify their widespread introduction.[677] Admission criteria are discussed elsewhere *(see section 6.2.6)*. 4

Criteria for and timing of discharge from hospital and emergency departments has been studied. The key event in recovery appears to be improved symptoms and peak flow rather than a complete return to normality. Discharge when improvement is apparent may be as safe as discharge when full stability is achieved. Asthma specialist nurse education of adults and school-age (but not pre-school) children at or shortly after hospital attendance improves symptom control, self management and re-attendance rates.[678-683] 1+ 2++ 2+ 2-

Making an appointment for review in primary care prior to discharge improves follow-up rates (but not outcomes).[684] Review within 30 days after hospital attendance with acute asthma is associated with reduced risk of further acute episodes.[685] There is most evidence of benefit when follow up is provided by specialist nurses. Various types of follow up after an acute exacerbation have been evaluated including GP care, hospital outpatient, and telephone follow up.[680,686] There would appear to be little difference in outcome depending on place or personnel involved in follow up *(see section 6.6)*.[676] 3 1+

A **Discharge from hospital or the emergency department should be a planned, supervised event which includes self management planning. It may safely take place as soon as clinical improvement is apparent.**

A **All people attending hospital with acute exacerbations of asthma should be reviewed by a clinician with particular expertise in asthma management, preferably within 30 days.**

❖ *Audit the percentage of people receiving specialist nurse advice including self management planning before discharge.*

❖ *Audit the percentage of people reviewed within 30 days after hospital attendance with acute exacerbation of asthma.*

8.3 AUDIT

Audit is a moderately effective way to improve the process and probably outcome of care.[687] Its impact is increased if combined with other strategies to change clinician behaviour, for example outreach education programmes. Whilst trials of audit in asthma care are few, those showing benefits have tended to incorporate feedback data to clinicians on the process of care such as frequency of review, checking of inhaler technique or lung function measurement. Passive feedback of aggregated data, for instance on prescribing patterns, does not change practice.[688]

8.3.1 TYPES OF AUDIT IN ASTHMA CARE

National or regional audits of asthma deaths have focused attention on delivery of care for severe asthma. Some primary care trusts have PCT-wide programmes of audit which extract practice data electronically and feedback comparative data on process of care, promoting a benchmarking approach to quality improvement.[689] The GMS Quality and Outcomes Framework (QOF) links audit of asthma care to financial incentives. Critical event audit focuses on an adverse event such as an asthma death, or failure of delivery care. How effective these activities are in improving outcomes of asthma care is uncertain.

Common sense suggests that auditing activities shown to improve patient outcomes is worthwhile. This chapter links suggestions for audit to guideline recommendations. Audit datasets are available at www.brit-thoracic.org.uk.

8.3.2 SUMMARY OF RECOMMENDED AUDITS

Diagnosis

Audit the percentage of adults with an Asthma Control Questionnaire score recorded and an Asthma Control Questionnaire of >0.75.

Non-pharmacological management

Audit the percentage of patients and parents-to be with smoking status recorded and the percentage who have received smoking cessation advice.

Pharmacological management

Audit:

- *the percentage of patients with potential adverse effects of treatment, for example, the percentage of children prescribed or using >800 micrograms/day of inhaled beclametasone who are not under the care of a specialist respiratory physician*
- *the percentage of patients in whom there has been documented consideration of downward dose titration for inhaled corticosteroid*
- *the percentage of patients using >800 micrograms/day of inhaled beclametasone without documented consideration of add-on therapy*
- *the percentage of patients in whom there has been documented consideration of downward dose titration for inhaled corticosteroid.*

Inhaler devices

Audit the percentage of patients in whom there is a record of satisfactory inhaler technique.

Audit the percentage of patients using a spacer device for mild to moderately severe exacerbations.

Management of acute asthma

Audit the percentage of patients in whom key steps in the management of acute asthma have been followed, for example, the percentage with a PEF measurement, the percentage with a justified X-ray on admission to hospital, or the percentage receiving corticosteroid tablets in adequate dosage and duration.

Asthma in pregnancy

Audit:

- *the percentage of pregnant women with documented discussion of the need to continue β_2 agonists and inhaled corticosteroid medication in pregnancy*
- *the percentage of pregnant women and partners who smoke with documented advice on smoking cessation.*

Occupational asthma

Audit the number of adults with adult-onset asthma for whom an occupational cause has been considered.

Organisation and delivery of care

Audit:

- *the percentage of clinicians who have taken part in suitable asthma educational update within last two years*
- *the percentage of patients reviewed annually. Consider focusing on particular groups such as those overusing bronchodilators, patients on higher treatment steps, those with exacerbations or from groups with more complex needs*
- *asthma outcomes in relevant subgroups of the population*
- *the percentage of inpatients receiving care from specialist asthma nurse or chest physician*
- *the percentage of patients treated according to key guideline recommendations*
- *the percentage of people receiving specialist nurse advice including self management planning before discharge*
- *the percentage of people reviewed within 30 days after hospital attendance with acute exacerbation of asthma.*

Patient education and self management

Audit the percentage of patients receiving written action plans.

Concordance and compliance

Audit prescription requests to determine compliance.

9 Patient education and self management

9.1 SELF-MANAGEMENT EDUCATION AND PERSONALISED ASTHMA ACTION PLANS

Written personalised action plans as part of self management education have been shown to improve health outcomes for people with asthma.[407,678,679,682,690-710] The evidence is particularly good for those in secondary care with moderate to severe disease, and those who have had recent exacerbations where successful interventions have reduced hospitalisations and emergency department attendances in people with severe asthma.[682,705,711,712] A consistent finding in many studies has been improvement in patient outcomes such as self-efficacy, knowledge and confidence.[690,701-703,709,713-727] 1+

A **Patients with asthma should be offered self-management education that focuses on individual needs, and be reinforced by a written personalised action plan.**

A **Prior to discharge, in-patients should receive written personalised action plans, given by clinicians with expertise in asthma management.**

9.1.1 COMPONENTS OF A SELF MANAGEMENT PROGRAMME

Self management education is a multi-faceted intervention with wide variation in the construction of programmes.[728,729] One systematic review has identified key components associated with beneficial outcome *(see Table 13)*.[730] While self management programmes are effective, individual components are not effective in isolation reinforcing the need to support the provision of personalised action plans with patient education.[728,731] 1+

Successful programmes vary considerably, but encompass:

- Structured education, reinforced with written personal action plans, though the duration, intensity and format for delivery may vary.[690,729]
- Specific advice about recognising loss of asthma control, though this may be assessed by symptoms or peak flows or both.[678,679,690,692,696-698,728,730,732-735]
- Actions, summarised as two or three action points, to take if asthma deteriorates, including seeking emergency help, commencing oral steroids (which may include provision of an emergency course of steroid tablets) recommencing or temporarily increasing inhaled steroids, as appropriate to clinical severity.[730]

Some published studies report long, intensive programmes.[709,736-738] However, there is evidence that short programmes are as effective,[679,739] and that usual care can be raised to a standard that incorporates many of the core elements of the successful extensive programmes.[740,741] 1+

A **Introduce personalised action plans as part of a structured educational discussion.**

Checklist 1. Suggested content for an educational programme/discussion

This checklist is intended as an example, which health professionals should adapt to meet the needs of individual patients and/or carers. The purpose of education is to empower patients and/or carers to undertake self management more appropriately and effectively. Information given should be tailored to individual patient's social, emotional and disease status, and age. Different approaches are needed for different ages.

- Nature of the disease
- Nature of the treatment
- Identify areas where patient most wants treatment to have effect
- How to use the treatment
- Development of self monitoring/self assessment skills
- Negotiation of the personalised action plan in light of identified patient goals
- Recognition and management of acute exacerbations
- Appropriate allergen or trigger avoidance.

9.1.2 SELF MANAGEMENT PROGRAMMES IN SPECIFIC PATIENT GROUPS

A range of different patient populations are included in the trials. It cannot be assumed that a successful intervention in one setting will be feasible or appropriate in another. The greatest benefits are shown in those managed in secondary care.[682,711,712] Primary care studies have also shown benefit,[698,700,702,741] though effects are weaker, perhaps because clinical benefit is harder to demonstrate in people with mild asthma. Innovative approaches to self management education in teenagers (web-based, peer delivered within schools) appear to have more success than more traditional programmes.[699-701,706,709,742-744] A different approach may be needed for pre-school children, many of whom have viral induced wheeze.[683,745,746] There are no studies which specifically address the provision of self-management education to the elderly. Sub group analyses from UK trials have suggested that existing self-management programmes may be of less benefit in ethnic minority groups, but there is a lack of studies evaluating more appropriate interventions.[698,705]

Self management programmes will only achieve better health outcomes if the prescribed asthma treatment is appropriate and within guideline recommendations.[713,717] There is some evidence that ownership of a self management plan may attract better treatment (ie increased steroid provision from attending physicians).[682,698,701]

9.2 COMPLIANCE AND CONCORDANCE

The term compliance embodies a traditional model of prescriptive care which refers to the objectively measured usage of prescribed medication, or frequency of monitoring. Non-compliance may be intentional or unintentional. The term 'concordance' signifies a negotiated agreement between the professional and the patient. Non-concordance describes an inability of both parties to come to an understanding, not merely a failure of the patient to follow the health professional's instructions.[747] Studies which assess whether or not the patient believes that their behaviour is appropriate find correlations between beliefs about illness and medicine and concordance.[748,749] Achieving concordance is likely to improve (though not guarantee) compliance.

9.2.1 COMPLIANCE WITH MONITORING AND TREATMENT

Compliance with regular monitoring with peak flow meters, even in clinical drug trials is poor, with recorded daily use as low as 6%.[750, 751] The lack of evidence supporting long term peak flow monitoring,[647,735,752,753] however, does not negate the use of home charting at critical times: for example, at diagnosis and initial assessment, when assessing response to changes in treatment, as part of a personalised action plan during exacerbations.[735] Comparison should be with the patients' best peak flow (not predicted).[730]

Patients are more likely to under-use than over-use treatment[754-756] and under-use should be considered when there is a failure to control asthma symptoms. Patient self reporting and health care professional assessment both overestimate regular use of prophylactic medication.[754,755,757] Computer repeat-prescribing systems, widely available in general practice, provide a good indication of adherence with prescribed asthma regimens. Electronic monitoring, whilst the most accurate method, is only practical in clinical drug trials.[754]

☑ Computer repeat-prescribing systems provide a useful index of compliance.

☑ Where the patient agrees with the health professional that the action is appropriate compliance is more likely.

9.2.2 INTERVENTIONS TO IMPROVE COMPLIANCE AND CONCORDANCE

Compliance can be improved by simple written instructions and reminders of when to use medication.[758] There is a suggestion in the literature that interventions designed to improve communication between patients and health professionals achieve better programme adherence.[625,737,759] Presenting important information first and repeating it can improve patient recall.[760] Computer,[761] and innovative web-based self management programmes may increase use of regular medication.[762] Within managed care programmes, nurse-led telephone-based self management education supported by written information can increase the use of inhaled steroids.[763,764]

☑ Provide simple, verbal and written instructions and information on drug treatment for patients and carers.

There is insufficient evidence to make clear recommendations on how the broader issues of concordance may be improved. Some practical tips for improving compliance are given in checklist 2.

Checklist 2: Practical tips for improving concordance

Open-ended questions like "If we could make one thing better for your asthma what would it be?" may help to elicit a more patient-centred agenda.

Make it clear you are listening and responding to the patient's concerns and goals.

Reinforce practical information and negotiated treatment plans with written instruction.

Consider reminder strategies.

Recall patients who miss appointments.

9.3 IMPLEMENTATION IN PRACTICE

Successful interventions have been delivered by trained asthma healthcare professionals, in the UK usually doctors and nurses, though a quality improvement programme which trained professionals in asthma self management showed no impact on clinical outcomes.[678,679,690,692,694,765]

Three primary care studies explicitly link the provision of self management education with the facilitation of regular, structured review, consistent with the concept of 'guided self management'. All three increased ownership of personalised action plans and one showed a reduction in episodes of 'speech limiting wheeze'.[631,741,766] 1+

B **Initiatives which encourage regular, structured review explicitly incorporating self management education should be used to increase ownership of personalised action plans.**

9.4 PRACTICAL ADVICE

9.4.1 AVAILABLE RESOURCES

A number of resources are available to support health professionals, including the 'Be in Control' materials produced by Asthma UK. Annex 11 reproduces the Asthma UK personalised action plan available from their website www.asthma.org.uk/control. Additional support and information for patients and carers is also available from the Asthma UK website (www.asthma.org.uk) and their Adviceline run by asthma specialist nurses: 08457 01 02 03 which includes an interpreting service covering 22 languages and Typetalk.

9.4.2 GOOD PRACTICE POINTS

Every asthma consultation is an opportunity to review, reinforce and extend both knowledge and skills. This is true whether the patient is seen in primary care, the accident and emergency department or the outpatient clinic. It is important to recognise that education is a process and not a single event.

☑
- A hospital admission represents a window of opportunity to review self management skills. No patient should leave hospital without a written personalised action plan and the benefit may be greatest at first admission.
- An acute consultation offers the opportunity to determine what action the patient has already taken to deal with the exacerbation. Their self management strategy may be reinforced or refined and the need for consolidation at a routine follow up considered.
- A consultation for an upper respiratory tract infection or other known trigger is an opportunity to rehearse with the patient their self management in the event of their asthma deteriorating.
- Brief simple education linked to patient goals is most likely to be acceptable to patients.

Table 13. Summary of the key components of a personalised action plan (adapted from Gibson et al)[730]

Component of an action plan	Result	Practical considerations
Format of action points: Symptom vs peak flow triggered Standard written instructions Traffic light configuration	 Similar effect Consistently beneficial Not clearly better than standard instructions	Asthma UK action plans include both symptom triggers and peak flow levels at which action should be taken.
Number of action points 2-3 action points 4 action points	 Consistently beneficial Not clearly better than 2-3 points	Usual action points are: PEF <80% best: increase inhaled steroids PEF <60% best: commence oral steroids PEF <40% best: seek urgent medical advice
Peak expiratory flow (PEF) levels Based on percentage personal best PEF Based on percentage predicted PEF	 Consistently beneficial Not consistently better than usual care	Personal best should be assessed once treatment has been optimised and peak flows are stable. Best peak flow should be updated every few years in adults, and more frequently in growing children.
Treatment instructions Individualised using inhaled and oral steroids Individualised using oral steroids only Individualised using inhaled steroids	 Consistently beneficial Insufficient data to evaluate Insufficient data to evaluate	Patients may safely hold an emergency supply of prednisolone tablets for use if their symptoms continue to deteriorate and/or if their peak flow falls to 60% of their best. Increasing inhaled steroids is ineffective if patients are already taking moderate or high doses (≥400 mcg daily) and these patients should be advised to move straight to the oral steroid step. Those on low doses (eg 200 mcg) of inhaled steroids may be advised to increase the dose substantially (eg to 1,200 mcg daily) at the onset of a deterioration.[631] Any patients who have stopped medication should be reminded to recommence their inhaled steroids.

10 Development of the guideline

10.1 INTRODUCTION

The guideline has been developed by multidisciplinary groups of practising clinicians using a standard methodology based on a systematic review of the evidence. Further details about SIGN and the guideline development methodology are contained in "SIGN 50: A Guideline Developer's Handbook", available at **www.sign.ac.uk**

Development involved the work of ten different multidisciplinary evidence review groups, a steering group and an executive group, chaired jointly by Dr Bernard Higgins on behalf of the BTS and Dr Graham Douglas on behalf of SIGN.

All members of the guideline development group made declarations of interest and further details of these are available on request from the SIGN Executive. Guideline development and literature review expertise, support and facilitation were provided by the SIGN Executive.

10.2 EXECUTIVE AND STEERING GROUPS

Dr Graham Douglas* (Co-chair)	*Consultant Respiratory Physician, Aberdeen Royal Infirmary*
Dr Bernard Higgins* (Co-chair)	*Consultant Respiratory Physician, Freeman Hospital, Newcastle upon Tyne*
Professor Neil Barnes	*Consultant Respiratory Physician, Barts and The London NHS Trust*
Dr Anne Boyter	*Senior Lecturer, Strathclyde Institute of Pharmacy and Biomedical Sciences, Glasgow*
Professor Sherwood Burge	*Consultant Respiratory Physician, Birmingham Heartlands Hospital*
Dr Chris Cates*	*Senior Research Fellow, St George's, University of London*
Dr Gary Connett	*Consultant Paediatrician, Southampton General Hospital*
Dr Jon Couriel*	*Consultant in Paediatric Respiratory Medicine, Alder Hey Children's Hospital, Liverpool*
Dr Paul Cullinan	*Consultant Physician/Reader, Imperial College, London*
Mrs Sheila Edwards*	*Chief Executive, British Thoracic Society, London*
Ms Erica Evans	*Asthma Care Development Manager, Asthma UK, London*
Ms Monica Fletcher	*Chief Executive, Education for Health, Warwick*
Professor Chris Griffiths	*Professor of Primary Care, Institute of Health Science Education, London*
Dr Liam Heaney	*Senior Lecturer in Respiratory Medicine, Queen's University, Belfast*
Ms Michele Hilton Boon*	*Information Officer, SIGN Executive*
Dr Steve Holmes	*General Practitioner and Chair, General Practice Airways Group, Somerset*
Mrs Ruth McArthur	*Practice Nurse/National Training Co-ordinator, Education for Health, East Kilbride*
Dr Cathy Nelson-Piercy	*Consultant Obstetric Physician, St Thomas' Hospital, London*
Professor Martyn Partridge*	*Professor of Respiratory Medicine, Imperial College, London and Chief Medical Adviser, Asthma UK*
Dr James Paton*	*Reader and Honorary Consultant Paediatrician, Royal Hospital for Sick Children, Glasgow*

Professor Ian Pavord*	*Consultant Physician/Honorary Professor of Medicine, Glenfield Hospital, Leicester*
Ms Elaine Carnegie	*Asthma Policy Officer, Asthma UK, Scotland*
Dr Hilary Pinnock	*General Practitioner, Whitstable Medical Practice, Kent*
Dr Safia Qureshi*	*Programme Director, SIGN*
Professor Colin Robertson	*Consultant in Emergency Medicine, Edinburgh Royal Infirmary*
Professor Mike Shields	*Professor of Child Health, Queen's University, Belfast*
Professor John Warner	*Professor of Paediatrics and Head of Department, Imperial College, London*
Dr John White	*Consultant Respiratory Physician, York District Hospital*

* Executive group

10.3 EVIDENCE REVIEW GROUPS

DIAGNOSIS

Dr Jon Couriel (Co-chair)	*Consultant in Paediatric Respiratory Medicine, Royal Liverpool Children's Hospital*
Dr James Paton (Co-chair)	*Reader and Honorary Consultant Paediatrician, Royal Hospital for Sick Children, Glasgow*
Professor Ian Pavord (Co-chair)	*Consultant Physician/Honorary Professor of Medicine, Glenfield Hospital, Leicester*
Professor Justin Beilby	*Head of the Department of General Practice, University of Adelaide, Australia*
Professor Anne Chang	*Head of Child Health Division, Menzies School of Health Research, Darwin and Royal Children's Hospital, Brisbane, Australia*
Dr Peter Gibson	*Adult Respiratory Physician, John Hunter Chest Institute, New South Wales, Australia*
Professor Peter Helms	*Professor of Child Health, University of Aberdeen*
Dr Bernard Higgins	*Consultant Respiratory Physician, Freeman Hospital, Newcastle upon Tyne*
Mrs Ruth McArthur	*Practice Nurse/National Training Co-ordinator, Education for Health, East Kilbride*
Dr Sarah Mayell	*Specialist Registrar, Alder Hey Hospital, Liverpool*
Dr Dominick Shaw	*Specialist Registrar, City Hospital Campus, Nottingham*
Dr Mike Thomas	*Asthma UK Senior Research Fellow, University of Aberdeen/ General Practitioner, Gloucestershire*

NON-PHARMACOLOGICAL MANAGEMENT

Dr Paul Cullinan (Co-chair)	*Reader in Occupational and Environmental Lung Disease, Royal Brompton Hospital, London*
Professor John Warner (Co-chair)	*Professor of Paediatrics and Head of Department, Imperial College, London*
Dr David Bellamy	*General Practitioner, Bournemouth and Pool Primary Care Trust*
Dr Graham Devereux	*Consultant in Thoracic Medicine, Aberdeen Royal Infirmary*

Dr David Reilly	*Lead Consultant Physician, Glasgow Homoeopathic Hospital*
Dr Janet Rimmer	*Respiratory Physician, Darlinghurst, New South Wales, Australia*
Dr Lyn Smurthwaite	*Research Development Manager, Asthma UK, London*
Mrs Deryn Thompson	*Nursing Tutor, Division of Health Sciences, University of South Australia*

PHARMACOLOGICAL MANAGEMENT

Professor Neil Barnes (Co-chair)	*Consultant Respiratory Physician, Barts and The London NHS Trust*
Professor Mike Shields (Co-chair)	*Professor of Child Health, Queen's University, Belfast*
Dr Anne Boyter	*Senior Lecturer, Strathclyde Institute of Pharmacy and Biomedical Sciences, Glasgow*
Dr Steve Cunningham	*Consultant Paediatrician, Royal Hospital for Sick Children, Edinburgh*
Dr Graeme Currie	*Consultant Physician, Aberdeen Royal Infirmary*
Ms Grainne d'Ancona	*Lead Pharmacist for Medicine, Guys and St Thomas' Hospital, London*
Dr Mike McKean	*Consultant in Respiratory Paediatrics, Royal Victoria Infirmary, Newcastle upon Tyne*
Ms Linda Pearce	*Respiratory Nurse Consultant, West Suffolk Hospital*
Dr Savitha Pushparajah	*General Practitioner, London*
Dr Mike Smith	*Consultant Paediatrician, Craigavon Area Group Hospital, Northern Ireland*
Dr David Spencer	*Consultant Respiratory Paediatrician, Freeman Hospital, Newcastle upon Tyne*
Dr Alison Whittaker	*Consultant Physician, Newport Chest Clinic, Gwent*

INHALER DEVICES

Dr John White (Chair)	*Consultant Respiratory Physician, York District Hospital*
Dr Chris Cates	*Senior Research Fellow, St George's, University of London*
Professor Henry Chrystyn	*Head of Pharmacy, University of Huddersfield*
Ms Monica Fletcher	*Chief Executive, Education for Health, Warwick*
Sr Karen Heslop	*Respiratory Nurse Specialist, Royal Victoria Infirmary, Newcastle upon Tyne*
Dr Alex Horsley	*Specialist Registrar, Western General Hospital, Edinburgh*

MANAGEMENT OF ACUTE ASTHMA

Dr Gary Connett (Co-chair)	*Consultant Paediatrician, Southampton General Hospital*
Professor Colin Robertson (Co-chair)	*Consultant in Emergency Medicine, Edinburgh Royal Infirmary*
Dr Richard Chavasse	*Consultant in Respiratory Paediatrics, St Helier Hospital, Surrey*
Dr Graham Douglas	*Consultant Respiratory Physician, Aberdeen Royal Infirmary*

Dr Mike Greenstone	*Consultant Physician, Castle Hill Hospital, East Yorkshire*
Dr Nick Innes	*Consultant in Respiratory and General Medicine, The Ipswich Hospital*
Dr Mark Levy	*General Practitioner, The Kenton Bridge Medical Centre, Middlesex*
Dr Rob Niven	*Senior Lecturer in Respiratory Medicine, Whythenshawe Hospital, Manchester*
Dr Ronan O'Driscoll	*Respiratory Physician, Hope Hospital, Salford*
Dr Ed Paterson	*Specialist Registrar in Respiratory Medicine, Aberdeen Royal Infirmary*
Dr Colin Powell	*Consultant Paediatrician, University Hospital of Wales, Cardiff*
Dr Lindsay Reid	*Specialist Registrar in Emergency Medicine, Edinburgh Royal Infirmary*
Dr Peter Weller	*Consultant Paediatrician (Respiratory Medicine), Birmingham Children's Hospital*

DELIVERY/ ORGANISATION OF CARE

Professor Chris Griffiths (Chair)	*Professor of Primary Care, Institute of Health Science Education, London*
Ms Monica Fletcher	*Chief Executive, Education for Health, Warwick*
Professor David Price	*GPIAG Professor of Primary Care Respiratory Medicine, Foresterhill Health Centre, Aberdeen*
Dr Richard Russell	*Consultant Physician, Heatherwood and Wexham Park Hospitals, Berkshire*

PATIENT EDUCATION, SELF MANAGEMENT AND COMPLIANCE

Dr Hilary Pinnock (Chair)	*General Practitioner, Whitstable Medical Practice, Kent*
Dr Graham Douglas	*Consultant Respiratory Physician, Aberdeen Royal Infirmary*
Mrs Erica Evans	*Care Development Manager, Asthma UK, London*
Dr Liesl Osman	*Senior Research Fellow, Aberdeen Royal Infimary*

SPECIAL SITUATIONS

Difficult asthma

Dr Liam Heaney (Chair)	*Senior Lecturer in Respiratory Medicine, Queens University, Belfast*
Dr Chris Brightling	*Senior Clinical Research Fellow, Glenfield Hospital, Leicester*
Dr Andrew Menzies-Gow	*Consultant Respiratory Physician, Royal Brompton Hospital, London*
Dr Brian Smith	*South Australian State President of the Thoracic Society of Australia*
Dr Nicola Wilson	*Honorary Consultant Paediatrician, Royal Brompton Hospital, London*

Asthma in pregnancy

Dr Cathy Nelson-Piercy (Chair)	*Consultant Obstetric Physician, St Thomas' Hospital, London*
Dr Bernard Higgins	*Consultant Respiratory Physician, Freeman Hospital, Newcastle upon Tyne*
Dr Laura Price	*Research Fellow, Imperial College, London*

Occupational asthma

Dr Sherwood Burge (Chair)	*Consultant Respiratory Physician, Birmingham Heartlands Hospital*
Professor Anthony Frew	*Professor of Allergy and Respiratory Medicine, Brighton General Hospital*

10.4 DISSEMINATION GROUP

Professor Martyn Partridge (Chair)	*Professor of Respiratory Medicine, Imperial College, London and Chief Medical Adviser, Asthma UK*
Mrs Sheila Edwards	*Chief Executive, British Thoracic Society, London*
Ms Monica Fletcher	*Chief Executive, Education for Health, Warwick*
Dr Bernard Higgins	*Consultant Respiratory Physician, Freeman Hospital, Newcastle upon Tyne*
Dr Steve Holmes	*General Practitioner and Chair, General Practice Airways Group, Somerset*
Dr James Paton	*Reader and Honorary Consultant Paediatrician, Royal Hospital for Sick Children, Glasgow*
Dr Hilary Pinnock	*General Practitioner, Whitstable Medical Practice, Kent*
Dr Safia Qureshi	*Programme Director, SIGN*
Mrs Sally Welham	*Deputy Chief Executive, British Thoracic Society, London*

10.5 SYSTEMATIC LITERATURE REVIEW

The evidence base for this guideline built on the reviews carried out for the original (2003) version of the guideline and subsequent updates.

All searches covered the Cochrane Library, Embase, and Medline. See Annex 1 for details of the time period covered for each topic. A copy of the search narrative, including listings of strategies, is available on the SIGN website as part of the supporting material for this guideline.

10.6 CONSULTATION AND PEER REVIEW

10.6.1 CONSULTATION

The most recent changes to this guideline were presented for discussion in draft form at the Winter Meeting of the British Thoracic Society in December 2008. The draft guideline was also available on the SIGN and BTS websites for a limited period at this stage to allow those unable to attend the meeting to contribute to the development of the guideline.

10.6.2 SPECIALIST REVIEWERS

The guideline was also reviewed in draft form by the following independent expert referees, who were asked to comment primarily on the comprehensiveness and accuracy of interpretation of the evidence base supporting the recommendations in the guideline. SIGN and the BTS are very grateful to all of these experts for their contribution to the guideline.

Ms Charlotte Allen	*Clinical Nurse Specialist - Asthma, Princess Margaret Hospital, Perth, Australia*
Dr Sandra Anderson	*Principal Hospital Scientist, Royal Prince Alfred Hospital, Sydney, Australia*
Professor Richard Beasley	*Professor of Medicine, Medical Research Institute of New Zealand, Wellington*
Dr David A R Boldy	*Consultant Respiratory Physician, Pilgrim Hospital, Boston, Lincolnshire*
Professor Chris Brightling	*Wellcome Senior Clinical Fellow and Honorary Consultant, Institute for Lung Health,* Leicester
Ms Karen Burnett	*Lay representative, Inverness*
Ms Suzanne Clark	*Lay representative, Glasgow*
Mr Michael Dennis	*Deputy Head of Prescribing, Great Yarmouth and Waveney (Teaching) PCT, Suffolk*
Dr Kevin Gruffydd-Jones	*Respiratory Lead, Royal College of General Practitioners, Joint Policy Lead, General Practice Airways Group and General Practitioner, Box Surgery, Wiltshire*
Dr John Haughney	*General Practitioner, Alison Lea Medical Centre, East Kilbride*
Miss Tracy Horner	*Medicines Management Technician, Bexhill Hospital, East Sussex*
Dr Norman Johnson	*Chairman of the BTS Standards of Care Committee, British Thoracic Society, London*
Dr Duncan Keeley	*General Practitioner, Thame Health Centre, Oxon*
Professor Helen Redell	*Clinical Associate Professor, University of Sydney, Australia*
Dr Robert Scott-Jupp	*Consultant Paediatrician, Salisbury District Hospital, Salisbury*
Professor Anne Tattersfield	*Head of Respiratory Medicine, University of Nottingham*
Professor Neil C Thomson	*Professor of Respiratory Medicine, Gartnavel General Hospital, Glasgow*
Dr Mark Woodhead	*Consultant in General and Respiratory Medicine, Central Manchester and Manchester Children's University Hospitals*

Abbreviations

ABG	arterial blood gas
ABPA	allergic bronchopulmonary aspergillosis
ACT	Asthma Control Test
ACTH	adrenocorticotropic hormone
AQLQ	Asthma Quality of Life Questionnaire
BDP	beclometasone
BTS	British Thoracic Society
COPD	chronic obstructive pulmonary disease
CXR	chest X-ray
DPI	dry powder inhaler
ED	emergency department
ETS	environmental tobacco smoke
FENO	exhaled nitric oxide concentration
FEV_1	forced expiratory volume in one second
FVC	forced vital capacity
GMS	General Medical Services
GP	general practitioner
GRASSIC	Grampian Asthma Study in Integrated Care
HDU	high dependency unit
ICU	intensive care unit
IM	intramuscular
IOS	impulse oscillometry
LABA	long-acting β_2 agonist
MDI	metered dose inhaler
MHRA	Medicines and Healthcare products Regulatory Agency
n-3PUFA	omega-3 polyunsaturated fatty acid
NIV	non-invasive ventilation
NSAIDS	Non-steroidal anti-inflammatory drugs
PaCO2	partial pressure of carbon dioxide in arterial blood
PaO2	partial pressure of oxygen in arterial blood
PC20	the provocative concentration of bronchoconstrictor (eg methacholine) required to cause a 20% fall in FEV_1
PD20	the provocative dose of bronchoconstrictor (eg methacholine) required to cause a 20% fall in FEV_1
PEF	peak expiratory flow
PEF A%H	peak expiratory flow amplitude percent highest
PICU	paediatric intensive care unit
PN	practice nurse
ppb	parts per billion
QOF	Quality and Outcomes Framework
RCP	Royal College of Physicians
RCT	randomised controlled trial
RV	residual volume
SIGN	Scottish Intercollegiate Guidelines Network
SpO2	saturation of peripheral oxygen
sRaw	specific airways resistance
VEmax	ventilation at maximal exercise capacity

Annex 1

Summary of search histories by section

Literature searches to support the various sections of this guideline are conducted on a rolling basis. This summary indicates the currency of the searches supporting each section. Searches in all databases began with the earliest year available at that time, which varied from database to database; for example, searches in Embase extended back to 1980 and in CINAHL to 1982. Specific date coverage is provided for Medline. Detailed search strategies are available on the SIGN website in the supplementary material section.

Section 2 Diagnosis

Diagnosis in children

The search was last updated in April 2007. Coverage in Medline extends from 2003-2006. This search supplemented the broader search on diagnosis conducted for the original 2003 diagnosis section.

Diagnosis in adults; monitoring

The search was last updated in February 2006. Coverage in Medline extends from 1966-2005.

Section 3 Non-pharmacological management

The search was last updated in February 2006. Coverage in Medline extends from 1966-2005.

Section 4 Pharmacological management

The search was last updated in June 2008. Coverage in Medline extends from 1966-May 2008.

Section 5 Inhaler devices

The search was last updated in June 2008. Coverage in Medline extends from 1998-January 2008.

Section 6 Management of acute asthma

The search was last updated in June 2008. Coverage in Medline extends from 1966-2008.

Section 7 Special situations

Difficult asthma

The search was conducted in July 2007 and covered 1996-June 2007.

Asthma in pregnancy

The search was last updated in June 2008. Coverage in Medline extends from 1966-January 2008.

Occupational asthma

The search was last updated by SIGN in March 2003. In 2005, a systematic review by the British Occupational Health Research Foundation was used as the basis for updating this section.

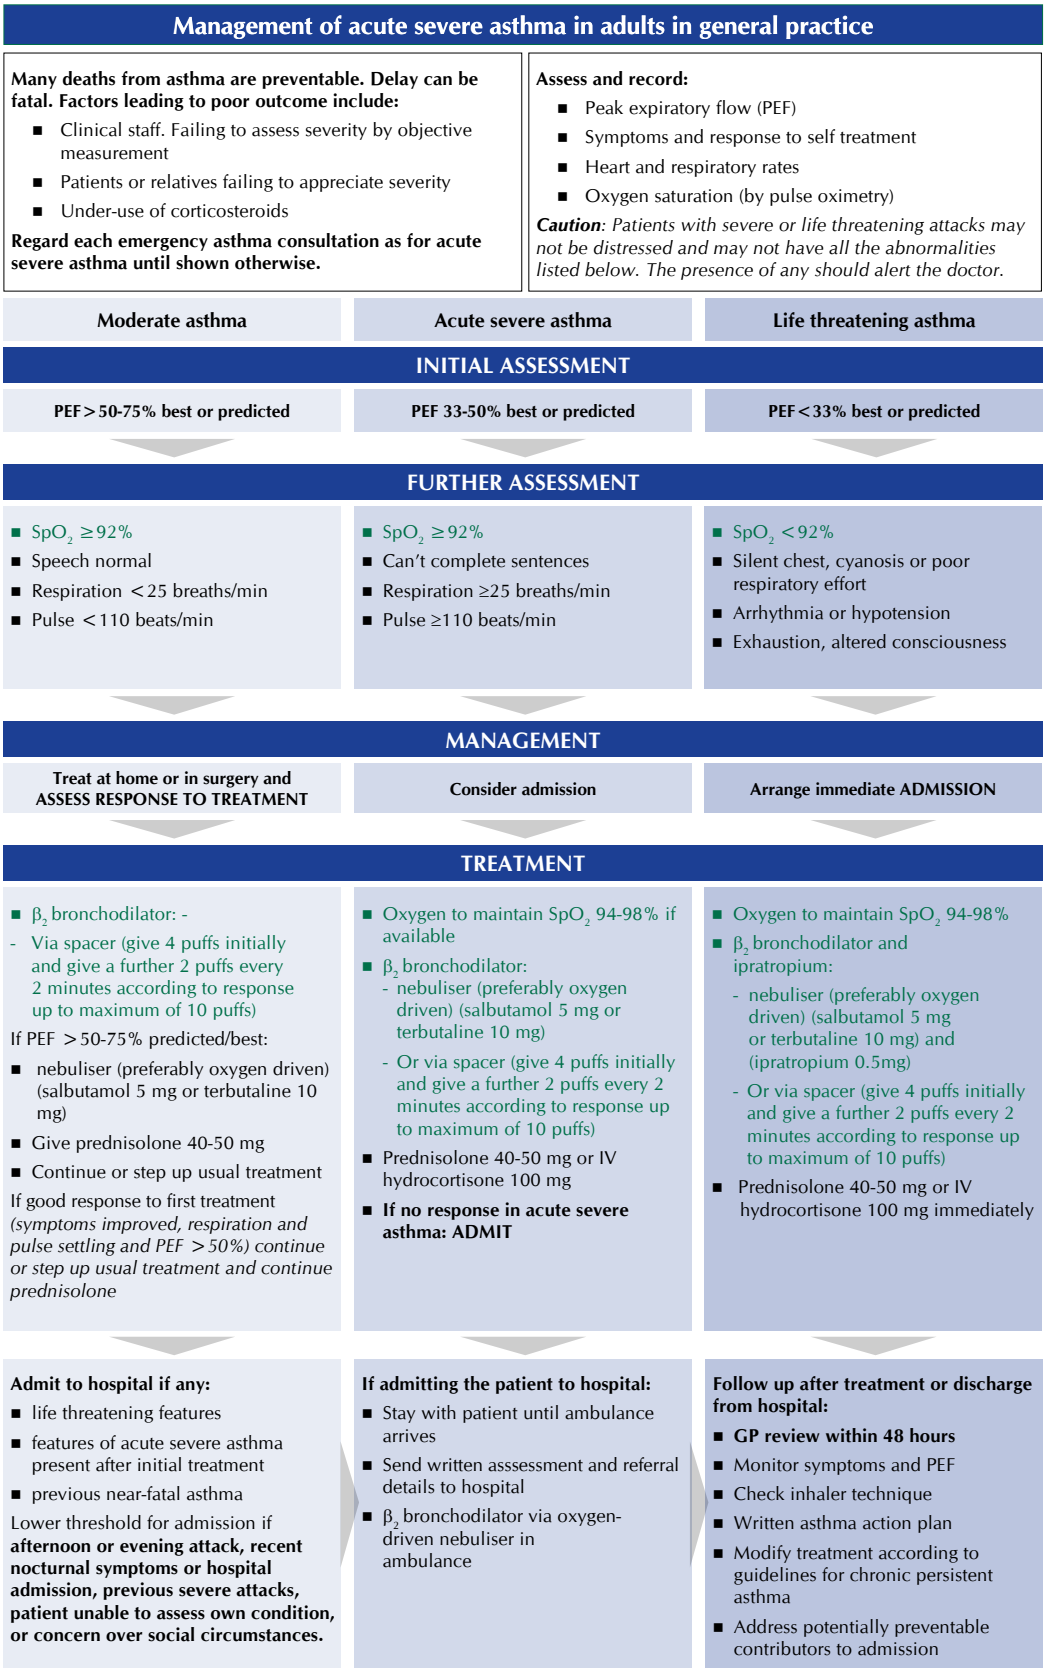
Section 8 Organisation and delivery of care, and audit

The search was last updated in March 2003. Coverage in Medline extends from 1966-2003.

Section 9 Patient education and self management

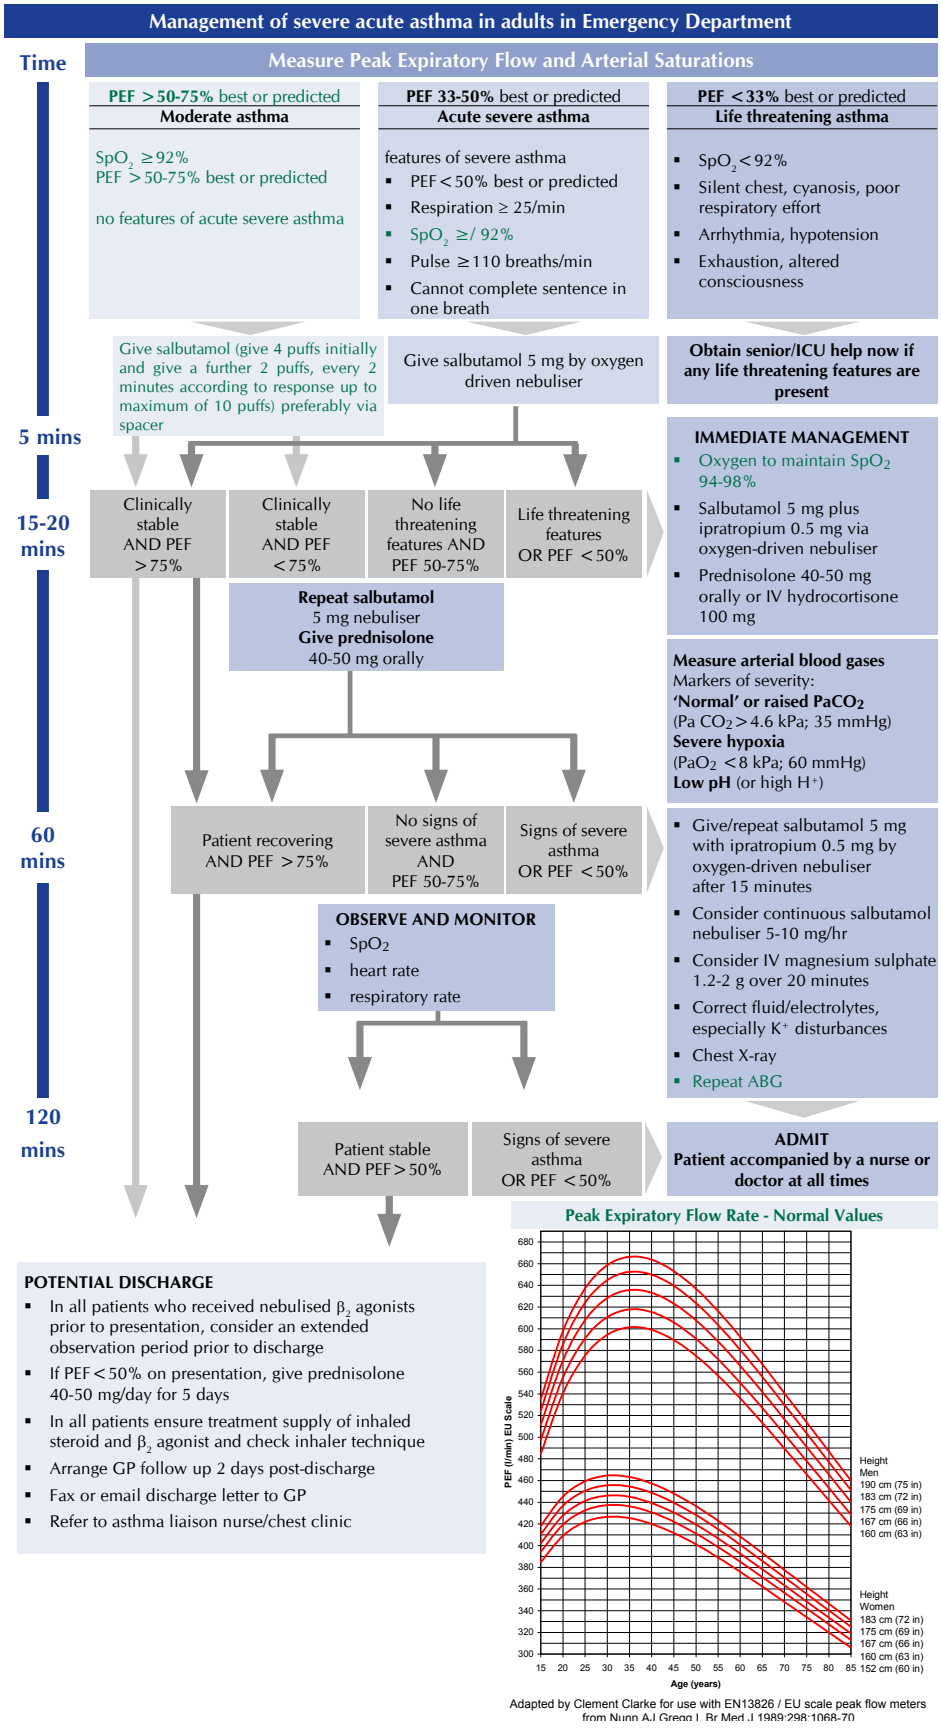
The search was last updated in February 2006. Coverage in Medline extends from 1966-2005.

Annex 2



Management of acute severe asthma in adults in general practice
Many deaths from asthma are preventable. Delay can be fatal. Factors leading to poor outcome include:
Clinical staff. Failing to assess severity by objective measurement
Patients or relatives failing to appreciate severity
Under-use of corticosteroids
Regard each emergency asthma consultation as for acute severe asthma until shown otherwise.
Assess and record:
Peak expiratory flow (PEF)
Symptoms and response to self treatment
Heart and respiratory rates
Oxygen saturation (by pulse oximetry)
Caution: Patients with severe or life threatening attacks may not be distressed and may not have all the abnormalities listed below. The presence of any should alert the doctor.
Moderate asthma
Acute severe asthma
Life threatening asthma
INITIAL ASSESSMENT
PEF > 50-75% best or predicted
PEF 33-50% best or predicted
PEF < 33% best or predicted
FURTHER ASSESSMENT
SpO2 ≥ 92%
Speech normal
Respiration < 25 breaths/min
Pulse < 110 beats/min
SpO2 ≥ 92%
Can't complete sentences
Respiration ≥25 breaths/min
Pulse ≥110 beats/min
SpO2 < 92%
Silent chest, cyanosis or poor respiratory effort
Arrhythmia or hypotension
Exhaustion, altered consciousness
MANAGEMENT
Treat at home or in surgery and ASSESS RESPONSE TO TREATMENT
Consider admission
Arrange immediate ADMISSION
TREATMENT
β2 bronchodilator: -
- Via spacer (give 4 puffs initially and give a further 2 puffs every 2 minutes according to response up to maximum of 10 puffs)
If PEF > 50-75% predicted/best:
nebuliser (preferably oxygen driven) (salbutamol 5 mg or terbutaline 10 mg)
Give prednisolone 40-50 mg
Continue or step up usual treatment
If good response to first treatment (symptoms improved, respiration and pulse settling and PEF > 50%) continue or step up usual treatment and continue prednisolone
Oxygen to maintain SpO2 94-98% if available
β2 bronchodilator:
- nebuliser (preferably oxygen driven) (salbutamol 5 mg or terbutaline 10 mg)
- Or via spacer (give 4 puffs initially and give a further 2 puffs every 2 minutes according to response up to maximum of 10 puffs)
Prednisolone 40-50 mg or IV hydrocortisone 100 mg
If no response in acute severe asthma: ADMIT
Oxygen to maintain SpO2 94-98%
β2 bronchodilator and ipratropium:
- nebuliser (preferably oxygen driven) (salbutamol 5 mg or terbutaline 10 mg) and (ipratropium 0.5mg)
- Or via spacer (give 4 puffs initially and give a further 2 puffs every 2 minutes according to response up to maximum of 10 puffs)
Prednisolone 40-50 mg or IV hydrocortisone 100 mg immediately
Admit to hospital if any:
life threatening features
features of acute severe asthma present after initial treatment
previous near-fatal asthma
Lower threshold for admission if afternoon or evening attack, recent nocturnal symptoms or hospital admission, previous severe attacks, patient unable to assess own condition, or concern over social circumstances.
If admitting the patient to hospital:
Stay with patient until ambulance arrives
Send written asssessment and referral details to hospital
β2 bronchodilator via oxygen-driven nebuliser in ambulance
Follow up after treatment or discharge from hospital:
GP review within 48 hours
Monitor symptoms and PEF
Check inhaler technique
Written asthma action plan
Modify treatment according to guidelines for chronic persistent asthma
Address potentially preventable contributors to admission

Annex 3



Management of severe acute asthma in adults in Emergency Department
Time
Measure Peak Expiratory Flow and Arterial Saturations
PEF >50-75% best or predicted
Moderate asthma
SpO2 ≥92%
PEF >50-75% best or predicted
no features of acute severe asthma
PEF 33-50% best or predicted
Acute severe asthma
features of severe asthma
PEF <50% best or predicted
Respiration ≥ 25/min
SpO2 ≥/ 92%
Pulse ≥110 breaths/min
Cannot complete sentence in one breath
PEF <33% best or predicted
Life threatening asthma
SpO2 <92%
Silent chest, cyanosis, poor respiratory effort
Arrhythmia, hypotension
Exhaustion, altered consciousness
Give salbutamol (give 4 puffs initially and give a further 2 puffs, every 2 minutes according to response up to maximum of 10 puffs) preferably via spacer
Give salbutamol 5 mg by oxygen driven nebuliser
Obtain senior/ICU help now if any life threatening features are present
5 mins
15-20 mins
Clinically stable AND PEF >75%
Clinically stable AND PEF <75%
No life threatening features AND PEF 50-75%
Life threatening features OR PEF <50%
IMMEDIATE MANAGEMENT
Oxygen to maintain SpO2 94-98%
Salbutamol 5 mg plus ipratropium 0.5 mg via oxygen-driven nebuliser
Prednisolone 40-50 mg orally or IV hydrocortisone 100 mg
Repeat salbutamol 5 mg nebuliser
Give prednisolone 40-50 mg orally
Measure arterial blood gases
Markers of severity:
'Normal' or raised PaCO2
(Pa CO2 >4.6 kPa; 35 mmHg)
Severe hypoxia
(PaO2 <8 kPa; 60 mmHg)
Low pH (or high H+)
60 mins
Patient recovering AND PEF >75%
No signs of severe asthma AND PEF 50-75%
Signs of severe asthma OR PEF <50%
Give/repeat salbutamol 5 mg with ipratropium 0.5 mg by oxygen-driven nebuliser after 15 minutes
Consider continuous salbutamol nebuliser 5-10 mg/hr
Consider IV magnesium sulphate 1.2-2 g over 20 minutes
Correct fluid/electrolytes, especially K+ disturbances
Chest X-ray
Repeat ABG
OBSERVE AND MONITOR
SpO2
heart rate
respiratory rate
120 mins
Patient stable AND PEF >50%
Signs of severe asthma OR PEF <50%
ADMIT
Patient accompanied by a nurse or doctor at all times
POTENTIAL DISCHARGE
In all patients who received nebulised β2 agonists prior to presentation, consider an extended observation period prior to discharge
If PEF <50% on presentation, give prednisolone 40-50 mg/day for 5 days
In all patients ensure treatment supply of inhaled steroid and β2 agonist and check inhaler technique
Arrange GP follow up 2 days post-discharge
Fax or email discharge letter to GP
Refer to asthma liaison nurse/chest clinic

Annex 4

Management of acute severe asthma in adults in hospital

Features of acute severe asthma

- Peak expiratory flow (PEF) 33-50% of best (use % predicted if recent best unknown)
- Can't complete sentences in one breath
- Respirations ≥25 breaths/min
- Pulse ≥110 beats/min

Life threatening features

- PEF <33% of best or predicted
- SpO_2 <92%
- Silent chest, cyanosis, or feeble respiratory effort
- Arrhythmia or hypotension
- Exhaustion, altered consciousness

If a patient has any life threatening feature, measure arterial blood gases. No other investigations are needed for immediate management.

Blood gas markers of a life threatening attack:

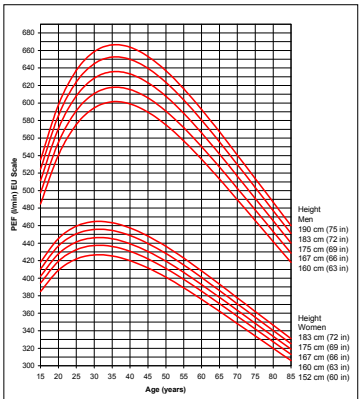
- 'Normal' (4.6-6 kPa, 35-45 mmHg) $PaCO_2$
- Severe hypoxia: PaO_2 <8 kPa (60mmHg) irrespective of treatment with oxygen
- A low pH (or high H^+)

Caution: Patients with severe or life threatening attacks may not be distressed and may not have all these abnormalities. The presence of any should alert the doctor.

Near fatal asthma

- Raised $PaCO_2$
- Requiring mechanical ventilation with raised inflation pressures

Peak Expiratory Flow Rate - Normal Values



Adapted by Clement Clarke for use with EN13826 / EU scale peak flow meters from Nunn AJ Gregg I, Br Med J 1989:298;1068-70

IMMEDIATE TREATMENT

- Oxygen to maintain SpO_2 94-98%
- Salbutamol 5 mg or terbutaline 10 mg via an oxygen-driven nebuliser
- Ipratropium bromide 0.5 mg via an oxygen-driven nebuliser
- Prednisolone tablets 40-50 mg or IV hydrocortisone 100 mg
- No sedatives of any kind
- Chest X ray if pneumothorax or consolidation are suspected or patient requires mechanical ventilation

IF LIFE THREATENING FEATURES ARE PRESENT:

- Discuss with senior clinician and ICU team
- Consider IV magnesium sulphate 1.2-2 g infusion over 20 minutes (unless already given)
- Give nebulised β_2 agonist more frequently e.g. salbutamol 5 mg up to every 15-30 minutes or 10 mg per hour via continuous nebulisation (requires special nebuliser)

SUBSEQUENT MANAGEMENT

IF PATIENT IS IMPROVING continue:

- Oxygen to maintain SpO_2 94-98%
- Prednisolone 40-50mg daily or IV hydrocortisone 100 mg 6 hourly
- Nebulised β_2 agonist and ipratropium 4-6 hourly

IF PATIENT NOT IMPROVING AFTER 15-30 MINUTES:

- Continue oxygen and steroids
- Use continuous nebulisation of salbutamol at 5-10 mg/hour if an appropriate nebuliser is available. Otherwise give nebulised salbutamol 5 mg every 15-30 minutes
- Continue ipratropium 0.5 mg 4-6 hourly until patient is improving

IF PATIENT IS STILL NOT IMPROVING:

- Discuss patient with senior clinician and ICU team
- Consider IV magnesium sulphate 1.2-2 g over 20 minutes (unless already given)
- Senior clinician may consider use of IV β_2 agonist or IV aminophylline or progression to mechanical ventilation

MONITORING

- Repeat measurement of PEF 15-30 minutes after starting treatment
- Oximetry: maintain SpO_2 >94-98%
- Repeat blood gas measurements within 1 hour of starting treatment if:
  - initial PaO_2 <8 kPa (60 mmHg) unless subsequent SpO_2 >92%
  - $PaCO_2$ normal or raised
  - patient deteriorates
- Chart PEF before and after giving β_2 agonists and at least 4 times daily throughout hospital stay

Transfer to ICU accompanied by a doctor prepared to intubate if:

- Deteriorating PEF, worsening or persisting hypoxia, or hypercapnea
- Exhaustion, altered consciousness
- Poor respiratory effort or respiratory arrest

DISCHARGE

When discharged from hospital, patients should have:

- Been on discharge medication for 12-24 hours and have had inhaler technique checked and recorded
- PEF >75% of best or predicted and PEF diurnal variability <25% unless discharge is agreed with respiratory physician
- Treatment with **oral and inhaled steroids** in addition to bronchodilators
- Own PEF meter and **written asthma action plan**
- GP follow up arranged within 2 working days
- Follow up appointment in respiratory clinic within 4 weeks

Patients with severe asthma (indicated by need for admission) **and adverse behavioural or psychosocial features are at risk of further severe or fatal attacks**

- Determine reason(s) for exacerbation and admission
- Send details of admission, discharge and potential best PEF to GP

Annex 5

Management of acute asthma in children in general practice

Age 2-5 years

ASSESS ASTHMA SEVERITY

Moderate asthma	Severe asthma	Life threatening asthma
■ SpO_2 ≥92% ■ Able to talk ■ Heart rate ≤140/min ■ Respiratory rate ≤40/min	■ SpO_2 <92% ■ Too breathless to talk ■ Heart rate >140/min ■ Respiratory rate >40/min ■ Use of accessory neck muscles	SpO_2 <92% plus any of: ■ Silent chest ■ Poor respiratory effort ■ Agitation ■ Altered consciousness ■ Cyanosis
■ β_2 agonist 2-10 puffs via spacer ± facemask ■ Consider soluble prednisolone 20 mg	■ Oxygen via face mask ■ 2-10 puffs of β_2 agonist [give 2 puffs, every 2 minutes according to response up to maximum of 10 puffs] or nebulised salbutamol 2.5 mg or terbutaline 5 mg ■ Soluble prednisolone 20 mg	■ Oxygen via face mask ■ Nebulise: - salbutamol 2.5 mg *or* terbutaline 5 mg + - ipratropium 0.25 mg ■ Soluble prednisolone 20 mg *or* IV hydrocortisone 50 mg
Increase β_2 agonist dose by 2 puffs every 2 minutes according to response up to 10 puffs	**Assess response to treatment 15 mins after β_2 agonist**	
IF POOR RESPONSE ARRANGE ADMISSION	**IF POOR RESPONSE REPEAT β_2 AGONIST AND ARRANGE ADMISSION**	**REPEAT β_2 AGONIST VIA OXYGEN-DRIVEN NEBULISER WHILST ARRANGING IMMEDIATE HOSPITAL ADMISSION**

GOOD RESPONSE
- Continue β_2 agonist via spacer or nebuliser, as needed but not exceeding 4-hourly
- **If symptoms are not controlled repeat β_2 agonist and refer to hospital**
- Continue prednisolone for up to 3 days
- Arrange follow-up clinic visit

POOR RESPONSE
- Stay with patient until ambulance arrives
- Send written assessment and referral details
- Repeat β_2 agonist via oxygen-driven nebuliser in ambulance

LOWER THRESHOLD FOR ADMISSION IF:
- Attack in late afternoon or at night
- Recent hospital admission or previous severe attack
- Concern over social circumstances or ability to cope at home

NB: If a patient has signs and symptoms across categories, always treat according to their most severe features

Age >5 years

ASSESS ASTHMA SEVERITY

Moderate asthma	Severe asthma	Life threatening asthma
■ SpO_2 ≥92% ■ PEF ≥50% best or predicted ■ Able to talk ■ Heart rate ≤125/min ■ Respiratory rate ≤30/min	■ SpO_2 <92% ■ PEF 33-50% best or predicted ■ Too breathless to talk ■ Heart rate >125/min ■ Respiratory rate >30/min ■ Use of accessory neck muscles	SpO_2 <92% plus any of: ■ PEF <33% best or predicted ■ Silent chest ■ Poor respiratory effort ■ Agitation ■ Altered consciousness ■ Cyanosis
■ β_2 agonist 2-10 puffs via spacer ■ Consider soluble prednisolone 30-40 mg	■ Oxygen via face mask ■ 2-10 puffs of β_2 agonist [give 2 puffs, every 2 minutes according to response up to maximum of 10 puffs] or nebulised salbutamol 2.5-5 mg or terbutaline 5-10 mg ■ Soluble prednisolone 30-40 mg	■ Oxygen via face mask ■ Nebulise: - salbutamol 5 mg *or* terbutaline 10 mg + - ipratropium 0.25 mg ■ Soluble prednisolone 30-40 mg *or* IV hydrocortisone 100 mg
Increase β_2 agonist dose by 2 puffs every 2 minutes according to response up to 10 puffs	**Assess response to treatment 15 mins after β_2 agonist**	
IF POOR RESPONSE ARRANGE ADMISSION	**IF POOR RESPONSE REPEAT β_2 AGONIST AND ARRANGE ADMISSION**	**REPEAT β_2 AGONIST VIA OXYGEN-DRIVEN NEBULISER WHILST ARRANGING IMMEDIATE HOSPITAL ADMISSION**

GOOD RESPONSE
- Continue β_2 agonist via spacer or nebuliser, as needed but not exceeding 4-hourly
- **If symptoms are not controlled repeat β_2 agonist and refer to hospital**
- Continue prednisolone for up to 3 days
- Arrange follow-up clinic visit

POOR RESPONSE
- Stay with patient until ambulance arrives
- Send written assessment and referral details
- Repeat β_2 agonist via oxygen-driven nebuliser in ambulance

LOWER THRESHOLD FOR ADMISSION IF:
- Attack in late afternoon or at night
- Recent hospital admission or previous severe attack
- Concern over social circumstances or ability to cope at home

NB: If a patient has signs and symptoms across categories, always treat according to their most severe features

Annex 6

Management of acute asthma in children in Emergency Department

Age 2-5 years

ASSESS ASTHMA SEVERITY

Moderate asthma
- SpO_2 ≥92%
- No clinical features of severe asthma

NB: If a patient has signs and symptoms across categories, always treat according to their most severe features

- β_2 agonist 2-10 puffs via spacer ± facemask [given one at a time single puffs, tidal breathing and inhaled separately]
- Increase β_2 agonist dose by 2 puffs every 2 minutes up to 10 puffs according to response
- Consider soluble oral prednisolone 20 mg

Reassess within 1 hour

DISCHARGE PLAN
- Continue β_2 agonist 4 hourly prn
- Consider prednisolone 20 mg daily for up to 3 days
- Advise to contact GP if not controlled on above treatment
- Provide a written asthma action plan
- Review regular treatment
- Check inhaler technique
- Arrange GP follow up

Severe asthma
- SpO_2 <92%
- Too breathless to talk or eat
- Heart rate >140/min
- Respiratory rate >40/min
- Use of accessory neck muscles

Oxygen via face mask/nasal prongs to achieve SpO_2 94-98%

- β_2 agonist 10 puffs via spacer ± facemask or nebulised salbutamol 2.5 mg or terbutaline 5 mg
- Soluble prednisolone 20 mg or IV hydrocortisone 4 mg/kg
- Repeat β_2 agonist up to every 20-30 minutes according to response
- **If poor response** add 0.25 mg nebulised ipratropium bromide

Life threatening asthma

SpO_2 <92% plus any of:
- Silent chest
- Poor respiratory effort
- Agitation
- Altered consciousness
- Cyanosis

- Nebulised β_2 agonist: salbutamol 2.5 mg or terbutaline 5 mg **plus** ipratropium bromide 0.25 mg nebulised
- Oral prednisolone 20mg or IV Hydrocortisone 4mg/kg if vomiting

Discuss with senior clinician, PICU team or paediatrician

- Repeat bronchodilators every 20-30 minutes

Arrange immediate transfer to PICU/HDU if poor response to treatment

Admit all cases if features of severe exacerbation persist after initial treatment

Age >5 years

ASSESS ASTHMA SEVERITY

Moderate asthma
- SpO_2 ≥92%
- PEF ≥50% best or predicted
- No clinical features of severe asthma

NB: If a patient has signs and symptoms across categories, always treat according to their most severe features

- β_2 agonist 2-10 puffs via spacer
- Increase β_2 agonist dose by 2 puffs every 2 minutes up to 10 puffs according to response
- Oral prednisolone 30-40 mg

Reassess within 1 hour

DISCHARGE PLAN
- Continue β_2 agonist 4 hourly as necessary
- Consider prednisolone 30-40 mg daily for up to 3 days
- Advise to contact GP if not controlled on above treatment
- Provide a written asthma action plan
- Review regular treatment
- Check inhaler technique
- Arrange GP follow up

Severe asthma
- SpO_2 <92%
- PEF 33-50% best or predicted
- Heart rate >125/min
- Respiratory rate >30/min
- Use of accessory neck muscles

Oxygen via face mask/nasal prongs to achieve SpO_2 94-98%

- β_2 agonist 10 puffs via spacer or nebulised salbutamol 2.5-5 mg or terbutaline 5-10 mg
- Oral prednisolone 30-40 mg or IV hydrocortisone 4 mg/kg if vomiting
- **If poor response** nebulised ipratropium bromide 0.25 mg
- Repeat β2 agonist and ipratropium up to every 20-30 minutes according to response

Life threatening asthma

SpO_2 <92% plus any of:
- PEF <33% best or predicted
- Silent chest
- Poor respiratory effort
- Altered consciousness
- Cyanosis

- Nebulised β_2 agonist: salbutamol 5 mg or terbutaline 10 mg **plus** ipratropium bromide 0.25 mg nebulised
- Oral prednisolone 30-40mg or IV Hydrocortisone 4mg/kg if vomiting

Discuss with senior clinician, PICU team or paediatrician

- Repeat bronchodilators every 20-30 minutes

Arrange immediate transfer to PICU/HDU if poor response to treatment

Admit all cases if features of severe exacerbation persist after initial treatment

Annex 7

Management of acute asthma in children in hospital

Age 2-5 years

ASSESS ASTHMA SEVERITY

Moderate asthma
- SpO_2 ≥92%
- No clinical features of severe asthma

NB: If a patient has signs and symptoms across categories, always treat according to their most severe features

- β_2 agonist 2-10 puffs via spacer ± facemask [given one at a time single puffs, tidal breathing and inhaled separately]
- Increase β_2 agonist dose by 2 puffs every 2 minutes up to 10 puffs according to response
- Consider soluble oral prednisolone 20 mg

Reassess within 1 hour

Severe asthma
- SpO_2 <92%
- Too breathless to talk or eat
- Heart rate >140/min
- Respiratory rate >40/min
- Use of accessory neck muscles

Life threatening asthma

SpO_2 <92% plus any of:
- Silent chest
- Poor respiratory effort
- Agitation
- Altered consciousness
- Cyanosis

Oxygen via face mask/nasal prongs to achieve SpO_2 94-98%

- β_2 agonist 10 puffs via spacer ± facemask or nebulised salbutamol 2.5 mg or terbutaline 5 mg
- Soluble prednisolone 20 mg or IV hydrocortisone 4 mg/kg
- Repeat β_2 agonist up to every 20-30 minutes according to response
- **If poor response** add 0.25 mg nebulised ipratropium bromide

- Nebulised β_2 agonist: salbutamol 2.5 mg or terbutaline 5 mg **plus** ipratropium bromide 0.25 mg nebulised
- Oral prednisolone 20mg or IV hydrocortisone 4mg/kg if vomiting

Discuss with senior clinician, PICU team or paediatrician

- Repeat bronchodilators every 20-30 minutes

ASSESS RESPONSE TO TREATMENT
Record respiratory rate, heart rate and oxygen saturation every 1-4 hours

RESPONDING
- Continue bronchodilators 1-4 hours prn
- Discharge when stable on 4 hourly treatment
- Continue oral prednisolone for up to 3 days

At discharge
- Ensure stable on 4 hourly inhaled treatment
- Review the need for regular treatment and the use of inhaled steroids
- Review inhaler technique
- Provide a written asthma action plan for treating future attacks
- Arrange follow up according to local policy

NOT RESPONDING
- **Arrange HDU/PICU transfer**

Consider:
- **Chest X-ray and blood gases**
- **IV salbutamol** 15 mcg/kg bolus over 10 minutes **followed** by continuous infusion 1-5 mcg/kg/min (dilute to 200 mcg/ml)
- **IV aminophylline** 5 mg/kg loading dose over 20 minutes (omit in those receiving oral theophyllines) **followed by** continuous infusion 1 mg/kg/hour

Age >5 years

ASSESS ASTHMA SEVERITY

Moderate asthma
- SpO_2 ≥92%
- PEF >50% best or predicted
- No clinical features of severe asthma

NB: If a patient has signs and symptoms across categories, always treat according to their most severe features

- β_2 agonist 2-10 puffs via spacer
- Increase β_2 agonist dose by 2 puffs every 2 minutes up to 10 puffs according to response
- Oral prednisolone 30-40 mg

Reassess within 1 hour

Severe asthma
- SpO_2 <92%
- PEF 33-50% best or predicted
- Heart rate >125/min
- Respiratory rate >30/min
- Use of accessory neck muscles

Oxygen via face mask/nasal prongs to achieve SpO_2 94-98%

- β_2 agonist 10 puffs via spacer or nebulised salbutamol 2.5-5 mg or terbutaline 5-10 mg
- Oral prednisolone 30-40 mg or IV hydrocortisone 4 mg/kg if vomiting
- **If poor response** nebulised ipratropium bromide 0.25 mg
- Repeat β2 agonist and ipratropium up to every 20-30 minutes according to response

Life threatening asthma

SpO_2 <92% plus any of:
- PEF <33% best or predicted
- Silent chest
- Poor respiratory effort
- Altered consciousness
- Cyanosis

- Nebulised β_2 agonist: salbutamol 5 mg or terbutaline 10 mg **plus** ipratropium bromide 0.25 mg nebulised
- Oral prednisolone 30-40mg or IV hydrocortisone 4mg/kg if vomiting

Discuss with senior clinician, PICU team or paediatrician

- Repeat bronchodilators every 20-30 minutes

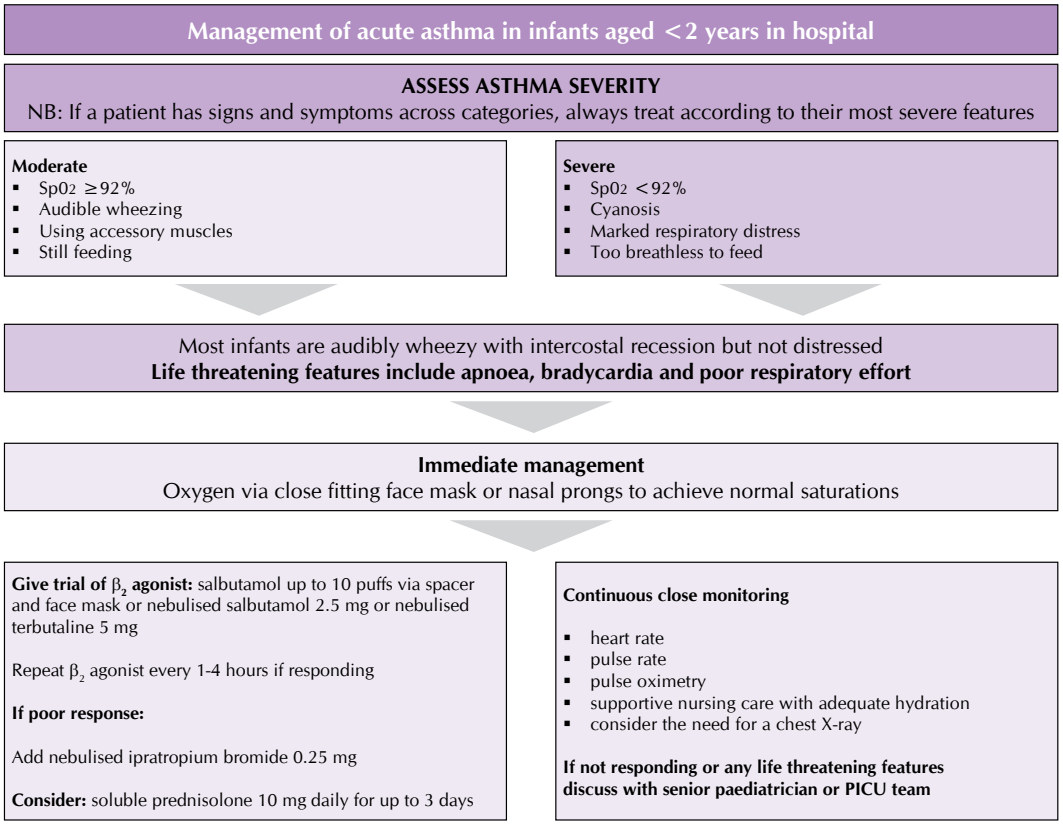
ASSESS RESPONSE TO TREATMENT
Record respiratory rate, heart rate, oxygen saturation and PEF/FEV every 1-4 hours

RESPONDING
- Continue bronchodilators 1-4 hours prn
- Discharge when stable on 4 hourly treatment
- Continue oral prednisolone 30-40 mg for up to 3 days

At discharge
- Ensure stable on 4 hourly inhaled treatment
- Review the need for regular treatment and the use of inhaled steroids
- Review inhaler technique
- Provide a written asthma action plan for treating future attacks
- Arrange follow up according to local policy

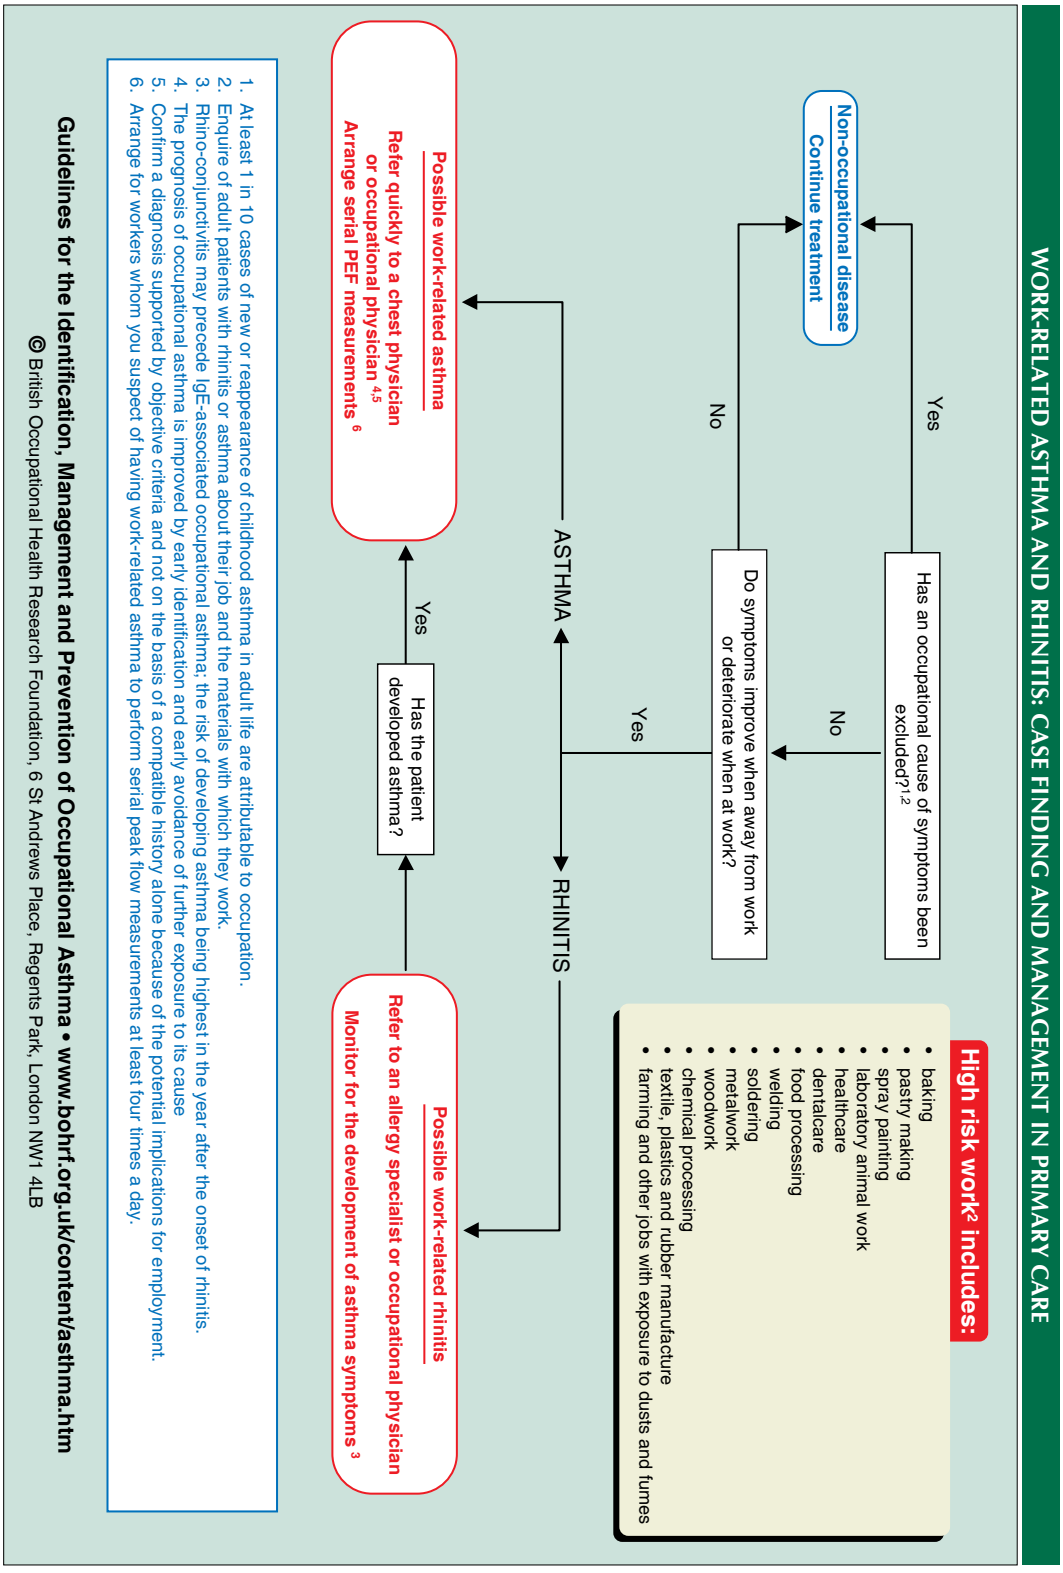
NOT RESPONDING
- **Continue 20-30 minute nebulisers and arrange HDU/PICU transfer**
- Consider: **Chest X-ray and blood gases**
- **Consider risks and benefits of:**
- **Bolus IV salbutamol** 15 mcg/kg if not already given
- Continuous **IV salbutamol infusion** 1-5 mcg/kg/min (200 mcg/ml solution)
- **IV aminophylline** 5 mg/kg loading dose over 20 minutes (omit in those receiving oral theophyllines) **followed by** continuous infusion 1mg/kg/hour
- **Bolus IV infusion of magnesium sulphate** 40 mg/kg (max 2 g) over 20 minutes

Annex 8



Management of acute asthma in infants aged < 2 years in hospital
ASSESS ASTHMA SEVERITY
NB: If a patient has signs and symptoms across categories, always treat according to their most severe features
Moderate
Sp02 ≥92%
Audible wheezing
Using accessory muscles
Still feeding
Severe
Sp02 <92%
Cyanosis
Marked respiratory distress
Too breathless to feed
Most infants are audibly wheezy with intercostal recession but not distressed
Life threatening features include apnoea, bradycardia and poor respiratory effort
Immediate management
Oxygen via close fitting face mask or nasal prongs to achieve normal saturations
Give trial of β2 agonist: salbutamol up to 10 puffs via spacer and face mask or nebulised salbutamol 2.5 mg or nebulised terbutaline 5 mg
Repeat β2 agonist every 1-4 hours if responding
If poor response:
Add nebulised ipratropium bromide 0.25 mg
Consider: soluble prednisolone 10 mg daily for up to 3 days
Continuous close monitoring
heart rate
pulse rate
pulse oximetry
supportive nursing care with adequate hydration
consider the need for a chest X-ray
If not responding or any life threatening features discuss with senior paediatrician or PICU team

Annex 9



WORK-RELATED ASTHMA AND RHINITIS: CASE FINDING AND MANAGEMENT IN PRIMARY CARE
Has an occupational cause of symptoms been excluded?[1,2]
Yes
No
Non-occupational disease
Continue treatment
Do symptoms improve when away from work or deteriorate when at work?
No
Yes
ASTHMA
RHINITIS
Has the patient developed asthma?
Yes
Possible work-related asthma
Refer quickly to a chest physician or occupational physician [4,5]
Arrange serial PEF measurements [6]
Possible work-related rhinitis
Refer to an allergy specialist or occupational physician
Monitor for the development of asthma symptoms [3]
High risk work[2] includes:
baking
pastry making
spray painting
laboratory animal work
healthcare
dentalcare
food processing
welding
soldering
metalwork
woodwork
chemical processing
textile, plastics and rubber manufacture
farming and other jobs with exposure to dusts and fumes
1. At least 1 in 10 cases of new or reappearance of childhood asthma in adult life are attributable to occupation.
2. Enquire of adult patients with rhinitis or asthma about their job and the materials with which they work.
3. Rhino-conjunctivitis may precede IgE-associated occupational asthma; the risk of developing asthma being highest in the year after the onset of rhinitis.
4. The prognosis of occupational asthma is improved by early identification and early avoidance of further exposure to its cause
5. Confirm a diagnosis supported by objective criteria and not on the basis of a compatible history alone because of the potential implications for employment.
6. Arrange for workers whom you suspect of having work-related asthma to perform serial peak flow measurements at least four times a day.

Annex 11

About your personal asthma action plan
This plan is intended to be used by people with asthma aged 12 and above.
Your doctor or nurse will fill in this plan with you and explain the different medicines that you should take to control your asthma. It shows you how to recognise when your asthma is getting worse and what you can do about it.
It is reassuring to know that by taking steps early, severe asthma attacks can usually be prevented.
Updating your personal asthma action plan
Because your asthma symptoms can change from day to day, your doctor or nurse may need to change your plan. You should have your asthma reviewed at least once a year.
If your medicine has been changed or increased, visit your doctor or nurse after one month to review your asthma.
Do not stop taking your asthma medicines without talking to your doctor or nurse first.
What to do in an asthma attack
An emergency is when any of the following happen:
1 Your reliever (blue) inhaler does not help
2 Your symptoms get worse (coughs, breathless, wheeze, tight chest)
3 You are too breathless to speak
What you must do during an attack:
1 Take your reliever (blue) inhaler
2 Sit up and loosen tight clothing
3 If no immediate improvement during an attack continue to take one puff of reliever inhaler every minute for five minutes or until symptoms improve
4 If your symptoms do not improve in five minutes – get it NOW (it is fatal – call 999 or a doctor urgently)

Doctor or nurse contact number
Growing what asthma medicines to take and when to take them is a vital first step towards keeping your asthma symptoms to an absolute minimum.
Be in control
What you can do
Make sure you are taking your medicines as discussed with your doctor or nurse – this information should be written in this card.
Ask your doctor or nurse for a personal asthma action plan. This will help you to know what to do if your symptoms get worse or do not improve.

Question: 1 of 100

Which of the following statements regarding bariatric surgery is correct?

(Please select 1 option)

- Associated with a significant post-operative mortality
- Associated with nutritional deficiencies
- Contraindicated in adolescents
- Indicated in patients with a BMI <35 kg/m^2
- Reduces cardiovascular mortality

Work Smart Session - MRCP Part 1

Time taken: 16 mins 6 secs

Question: 10 of 100

A 39-year-old female presents with lethargy, nausea, and muscle cramps; and she has passed 450 ml of urine in the last 24 hours.

She was recently started on a new medication.

Serum sodium	128 mmol/l	(137-144)
Plasma osmolality	272 mosmol/l	(275-290)
Urine osmolality	380 mosmol/l	(350-1000)

Which of the following recently prescribed drugs accounts for the findings?

(Please select 1 option)

- Aspirin
- Fluoxetine
- Furosemide
- Lithium
- Metoprolol

Work Smart Session - MRCP Part 1

Time taken: 4 hrs 30 mins 30 secs

Question: 100 of 100

A 39-year-old male presents with gynaecomastia.

Which of the following is the most likely cause of his gynaecomastia?

(Please select 1 option)

○	Congenital adrenal hyperplasia (CAH)
○	Hypopituitarism
○	Hypothyroidism
○	Prolactinoma
○	Seminoma

Submit answer | Skip question | Tag Question | Remove question

Question: 100 of 100

A 39-year-old male presents with gynaecomastia.

Which of the following is the most likely cause of his gynaecomastia?

(Please select 1 option)

○	Congenital adrenal hyperplasia (CAH)
○	Hypopituitarism
◉	Hypothyroidism ✕ Incorrect answer selected
○	Prolactinoma
○	Seminoma ← This is the correct answer

Gynaecomastia is due to a perturbation in the testosterone to oestradiol ratio.

Neither hyperprolactinaemia nor hypopituitarism disturb this ratio and are rarely associated with gynaecomastia.

Unlike hyperthyroidism, hypothyroidism is not a cause.

CAH is not a cause.

However, gynaecomastia may be a presenting symptom of a seminoma and may arise due to human chorionic gonadotropin (HCG) secretion.

Plasma osmolality	272 mosmol/l	(275-290)
Urine osmolality	380 mosmol/l	(350-1000)

Which of the following recently prescribed drugs accounts for the findings?

(Please select 1 option)

◉	Aspirin ✕ Incorrect answer selected
○	Fluoxetine ← This is the correct answer
○	Furosemide
○	Lithium
○	Metoprolol

This lady has

- Hyponatraemia
- Hypotonicity (low serum osmolality) and
- Inappropriately concentrated urine

which is consistent with syndrome of inappropriate antidiuretic hormone (ADH).

Of the drugs listed, fluoxetine is the most likely cause of syndrome of inappropriate secretion of antidiuretic hormone (SIADH).

Work Smart Session - MRCP Part 1

Time taken: 17 mins 32 secs

Question: 11 of 100

A 60-year-old patient with metastatic breast carcinoma attends clinic complaining of pain in the jaw and ulceration within the oral cavity which has persisted for four weeks following a dental extraction. She has had a course of antibiotic therapy for suspected secondary infection of the ulceration.

On examination there is ulceration within the oral cavity which extends as far as the underlying mandible.

Which of the following drugs is likely to be responsible for her presentation?

(Please select 1 option)

- Anastrozole
- Diclofenac
- Prednisolone
- Tamoxifen
- Zoledronic acid

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Which of the following drugs is likely to be responsible for her presentation?

(Please select 1 option)

○	Anastrozole
○	Diclofenac
○	Prednisolone
○	Tamoxifen
◉	Zoledronic acid ✓ Correct

The likely causative agent is the nitrogen containing bisphosphonate zoledronic acid.

The clinical scenario suggests a diagnosis of bisphosphonate associated osteonecrosis of the jaw. This is a recently recognised adverse effect of bisphosphonate therapy. This is a consequence of potent anti-resorptive action of the nitrogen containing bisphosphonates.

Most cases have been associated with zoledronic acid and pamidronate given intravenously for metastatic bone disease. The reported incidence in patients with malignancy treated with these drugs is between 1.3-4.0%.

Dental disease is a recognised predisposing factor.

The lesions usually heal with minimal surgical debridement, chlorhexidine mouthwashes, antibiotics and analgesia.

Work Smart Session - MRCP Part 1

Time taken: 18 mins 46 secs

Question: 12 of 100

A 64-year-old retired Caucasian solicitor attends the surgery. He is overweight and takes little exercise.

He has been treated for hypertension for five years and is controlled on 5 mg of ramipril. He also takes 20 mg of simvastatin for hypercholesterolaemia. A 75g oral glucose tolerance test was recently performed and gave a result consistent with impaired glucose tolerance (IGT) with a two hour plasma glucose concentration of 9.3 mmol/L (3.0-6.0). The patient is keen to know what would be his risk of developing type 2 diabetes.

What do you tell him?

(Please select 1 option)

○	6% over 6 years
○	10% over 6 years
○	33% over 6 years
◉	60% over 6 years
○	100% over 6 years

He has been treated for hypertension for five years and is controlled on 5 mg of ramipril. He also takes 20 mg of simvastatin for hypercholesterolaemia. A 75g oral glucose tolerance test was recently performed and gave a result consistent with impaired glucose tolerance (IGT) with a two hour plasma glucose concentration of 9.3 mmol/L (3.0-6.0). The patient is keen to know what would be his risk of developing type 2 diabetes.

What do you tell him?

(Please select 1 option)

○	6% over 6 years
○	10% over 6 years
◉	33% over 6 years ✓ Correct
○	60% over 6 years
○	100% over 6 years

Individuals with IGT are at significant risk of progression to type 2 diabetes.

A number of studies have looked at the absolute risk of progression from IGT to type 2 diabetes. The large and widely quoted Hoorn study which looked at 1342 Caucasian non-diabetic subjects found that 33.8% progressed to type 2 diabetes over six years follow up.

This increased to 64.5% if individuals had both IGT and IFG. A similar rate of progression for individuals with IGT was Vaccaro who studied a Caucasian group in Italy.

Intensive lifestyle changes involving diet changes, regular exercise and weight loss have been shown to reduce the rate of progression to type 2 diabetes.

Work Smart Session - MRCP Part 1

Time taken: 21 mins 18 secs

Question: 13 of 100

A 52-year-old male with a history of dyslipidaemia and hypertension attends the surgery for a 75 g oral glucose tolerance test (OGTT) as part of his cardiovascular risk assessment and screening for Type 2 diabetes. He is overweight with a BMI of 29 kg/m^2, his blood pressure is 135/85 mmHg on a combination of amlodipine and perindopril.

His venous plasma OGTT result is as follows:

0 minutes	6.3
120 minutes	10.4

Which of the following is the correct interpretation of these results?

(Please select 1 option)

- ○ Impaired fasting glucose (IFG)
- ○ Impaired fasting glucose and impaired glucose tolerance
- ○ Impaired glucose tolerance (IGT)
- ○ Normal glucose tolerance.
- ○ Type 2 diabetes

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Which of the following is the correct interpretation of these results?

(Please select 1 option)

○	Impaired fasting glucose (IFG)
◉	Impaired fasting glucose and impaired glucose tolerance ✓ Correct
○	Impaired glucose tolerance (IGT)
○	Normal glucose tolerance.
○	Type 2 diabetes

The World Health Organisation recommend the use of the OGTT for the diagnosis of Type 2 diabetes as it incorporates the fasting and two hour post-glucose load which can identify different sub-groups of diabetic patients and different categories of individuals at risk of Type 2 diabetes.

The diagnostic criteria are:

Venous plasma glucose	Fasting (mmol/l)	2 hour post glucose (mmol/l)
Diabetic	> 7.0	> 11.1
IGT	<7.0	7.8-11.0
IFG	6.1-6.9	<7.8

In the absence of marked hyperglycaemia and symptoms such as weight loss, polyuria or polydipsia these results should be confirmed by a repeat test on another day.

Work Smart Session - MRCP Part 1

Question: 14 of 100

A 26-year-old man presented with polydipsia and polyuria for the last two years.

Investigations reveal:

Serum urea	8.4 mmol/L (2.5-7.5)
Serum creatinine	108 mol/L (60-110)
Serum corrected calcium	2.82 mmol/L (2.2-2.6)
Serum phosphate	0.73 mmol/L (0.8-1.4)
Plasma parathyroid hormone	6.8 pmol/L (0.9-5.4)

Which of the following is directly responsible for his increased intestinal calcium reabsorption?

(Please select 1 option)

- 1,25 Dihydroxy vitamin D
- 25 Hydroxy vitamin D
- Calcitonin
- Hypophosphataemia
- Parathyroid hormone

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Investigations reveal:

Serum urea	8.4 mmol/L (2.5-7.5)
Serum creatinine	108 mol/L (60-110)
Serum corrected calcium	2.82 mmol/L (2.2-2.6)
Serum phosphate	0.73 mmol/L (0.8-1.4)
Plasma parathyroid hormone	6.8 pmol/L (0.9-5.4)

Which of the following is directly responsible for his increased intestinal calcium reabsorption?

(Please select 1 option)

- (●) 1,25 Dihydroxy vitamin D ✓ Correct
- ( ) 25 Hydroxy vitamin D
- ( ) Calcitonin
- ( ) Hypophosphataemia
- ( ) Parathyroid hormone

This patient has hypercalcaemia due to hyperparathyroidism.

However, the intestinal absorption of calcium is facilitated by 1,25 dihydroxy-vitamin D, which stimulates the microvillous membrane of the enterocyte to synthesise the calcium-binding carrier protein necessary for active calcium ion absorption .

Work Smart Session - MRCP Part 1

Question: 15 of 100

A 45-year-old male presents concerned about his risk of developing diabetes. His family history reveals that his mother and maternal uncle both have diabetes.

He has central obesity with a waist measurement of 110 cm.

On examination, his blood pressure is 130/82 mmHg, his BMI is 30.2 kg/m^2 .

His investigations reveal:

Fasting cholesterol	5.2 mmol/L	(<5.2)
Triglycerides	1.4 mmol/L	(0.45-1.69)
HDL cholesterol	1.1 mmol/L	(> 1.55)
Fasting glucose	6.2 mmol/L	(3.0-6.0)

In addition to his waist measurement which of this man's observations fulfills the criteria for the diagnosis of the metabolic syndrome?

(Please select 1 option)

- ○ Blood pressure of 130/82 mmHg
- ○ BMI of 30.2 kg/m^2
- ○ Fasting plasma glucose of 6.2 mmol/l
- ○ HDL concentration of 1.1 mmol/l
- ○ Triglyceride concentration of 1.4 mmol/l

Submit answer | Skip question | Tag Question | Remove question

syndrome?

(Please select 1 option)

○	Blood pressure of 130/82 mmHg
○	BMI of 30.2 kg/m^2
◉	Fasting plasma glucose of 6.2 mmol/l ✓ Correct
○	HDL concentration of 1.1 mmol/l
○	Triglyceride concentration of 1.4 mmol/l

The metabolic syndrome is becoming hugely important as a cluster of features associated with increased cardiovascular and diabetes risk.

The condition is defined by various criteria the latest of which is the global definition for the IDF as central obesity (>=94cm for men, >=80 cm for women) plus any two of the following:

- Hypertriglyceridaemia >1.7 mmol/l
- Low HDL concentration <1.03 mmol/l male, <1.29 mmol/l female
- BP > or = 130/85 mmHg, or on treatment for hypertension
- Fasting glucose > or = 5.6 mmol/l, or known to have type 2 diabetes.

Thus, in our patient's case the elevated fasting glucose of 6.3 mmol/l fulfills this diagnostic criterion.

The BMI is not a function of the diagnostic criteria as the waist circumference appears to be a far more powerful predictor of risk.

Work Smart Session - MRCP Part 1

Time taken: 28 mins 18 secs

Question: 16 of 100

A 29-year-old female with Turner syndrome is referred by the GP concerned about her blood pressure which he has found to be persistently elevated at between 140-160/90 mmHg.

On examination she is noted to have a blood pressure of 148/92 mmHg, with no radio-femoral delay and no murmur audible.

Which of the following is the most likely cause of her hypertension?

(Please select 1 option)

- Coarctation of the aorta
- Essential hypertension
- Primary hyperaldosteronism
- Renal artery stenosis
- Single horseshoe kidney

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 29 mins 18 secs

Question: 16 of 100

A 29-year-old female with Turner syndrome is referred by the GP concerned about her blood pressure which he has found to be persistently elevated at between 140-160/90 mmHg.

On examination she is noted to have a blood pressure of 148/92 mmHg, with no radio-femoral delay and no murmur audible.

Which of the following is the most likely cause of her hypertension?

(Please select 1 option)

◉	Coarctation of the aorta ✕ Incorrect answer selected
○	Essential hypertension ← This is the correct answer
○	Primary hyperaldosteronism
○	Renal artery stenosis
○	Single horseshoe kidney

Hypertension is quite common in Turner syndrome (10%) and is typically idiopathic - essential.

In a small proportion causes can include coarctation of the aorta and renal dysfunction due to horseshoe kidney.

In this case, essential hypertension is the most likely cause, but in the absence of specific features of coarctation this would again be the most appropriate option.

Work Smart Session - MRCP Part 1

Time taken: 29 mins 18 secs

Question: 17 of 100

A 41-year-old male on routine risk factor screening is noted to have a blood pressure of 146/86 mm/Hg.

His investigations reveal:

Fasting plasma glucose	5.8 mmol/L	(3.0-6.0)
Total cholesterol	6.2 mmol/L	(<5.2)
Triglyceride	12.8 mmol/L	(0.45-1.69)
HDL-cholesterol	0.8 mmol/L	(>1.55)

Which is the most appropriate treatment for his lipid profile?

(Please select 1 option)

- ○ Ezetimibe
- ○ Fenofibrate
- ○ Nicotinic acid slow release
- ○ Rosuvastatin
- ○ Simvastatin

Submit answer | Skip question | Tag Question | Remove question

Triglyceride	12.8 mmol/L	(0.45-1.69)
HDL-cholesterol	0.8 mmol/L	(>1.55)

Which is the most appropriate treatment for his lipid profile?

(Please select 1 option)

- Ezetimibe
- Fenofibrate
- Nicotinic acid slow release ← This is the correct answer
- Rosuvastatin
- Simvastatin ✕ Incorrect answer selected

This patient is likely to have type V hyperlipoproteinaemia characterised by an excess of triglyceride containing lipoproteins and an increased risk of pancreatitis.

Nicotinic acid primarily reduces plasma TG levels via inhibition of hepatic TG synthesis suppressing FFA supply to the liver. It is currently the most effective TG reducing pharmacotherapy producing reductions of up to 30% in plasma TG at a dose of 2 g a day.

Its use is limited by side effects mainly flushing and an exacerbation of insulin resistance. The flushing may be diminished by gradual dose escalation, consumption following a low fat snack and concomitant aspirin use.

Alternative therapies in the event of intolerance to nicotinic acid include fenofibrate as a good second choice or alternatively omega-3 fatty acids.

Question: 18 of 100

During routine investigation of a healthy couple for primary subfertility semen analysis reveals azoospermia.

On examination of the male there are no abnormalities on general examination and testicular examination shows a normal testicular volume.

Investigations reveal:

LH	5.1 IU/L	(2-10)
FSH	4.3 IU/L	(2-10)
Testosterone	15.3 nmol/L	(9-30)

Which of the following is the most likely cause of his azoospermia?

(Please select 1 option)

- Androgen insensitivity
- Genital tract obstruction
- Idiopathic testicular failure
- Kallman's Syndrome
- Sperm autoimmunity

Submit answer | Skip question | Tag Question | Remove question

Investigations reveal:

LH	5.1 IU/L	(2-10)
FSH	4.3 IU/L	(2-10)
Testosterone	15.3 nmol/L	(9-30)

Which of the following is the most likely cause of his azoospermia?

(Please select 1 option)

- Androgen insensitivity
- Genital tract obstruction ← This is the correct answer
- Idiopathic testicular failure
- Kallman's Syndrome
- Sperm autoimmunity ✕ Incorrect answer selected

The normal FSH and testosterone would exclude a primary testicular cause of the azoospermia and therefore would suggest obstruction such as agenesis of the vas as seen in cystic fibrosis.

Work Smart Session - MRCP Part 1

Time taken: 34 mins 45 secs

Question: 19 of 100

A 48-year-old woman presents with a history of intestinal polyps and multiple lipomas on the arms and back. She now has a small palpable nodule in her neck. Thyroid function tests and thyroid antibodies are normal.

Which of the following tumours is she at increased risk of developing?

(Please select 1 option)

○	Anaplastic carcinoma of the thyroid
○	Follicular carcinoma of the thyroid
○	Medullary carcinoma of the thyroid
○	Papillary carcinoma of the thyroid ← This is the correct answer
◉	Thyroid lymphoma ✕ Incorrect answer selected

This lady has Gardener's syndrome, or familial adenomatous polyposis, characterised by multiple small and large intestinal tumours and lipomas. Osteomata and fibromas are also seen.

It is a rare familial condition, when arising from mutations of the APC gene is inherited in an autosomal dominant fashion.

Gardener's syndrome carries an increased risk of papillary carcinoma of the thyroid with a preponderance for female patients.

Work Smart Session - MRCP Part 1

Time taken: 1 mins 21 secs

Question: 1 of 100

Which of the following statements regarding bariatric surgery is correct?

(Please select 1 option)

○	Associated with a significant post-operative mortality
◉	Associated with nutritional deficiencies ✓ Correct
○	Contraindicated in adolescents
○	Indicated in patients with a BMI <35 kg/m^2
○	Reduces cardiovascular mortality

Bariatric surgery is a major gastrointestinal procedure. Bariatric surgery in adolescents raises social, psychological and developmental issues, but adolescents are not excluded from surgery, and some hospitals have specialised programmes for younger patients.

Potential candidates for surgery are those with a body mass index (BMI) exceeding 40, or BMI >35 with serious co-morbidities (e.g. sleep apnoea, type 2 diabetes). Post-operative mortality ranges from 0.1-2%.

Vomiting is a risk associated with bariatric surgery, as is dumping syndrome and nutritional deficiencies. There is no evidence as yet, that bariatric surgery reduces cardiovascular mortality in patients.

Work Smart Session - MRCP Part 1

Time taken: 1 mins 21 secs

Question: 2 of 100

Whilst hospitalised after a hip replacement, a patient with acute intermittent porphyria (AIP) has an epileptic seizure. The seizure was thought to have been due to alcohol withdrawal.

The patient requires large amounts of analgesia. Six days post-operatively she suffers a porphyric attack.

Which of the following drugs on her prescription is likely to have been responsible?

(Please select 1 option)

- Aspirin
- Augmentin
- Oramorph
- Paracetamol
- Sodium valproate

Work Smart Session - MRCP Part 1

Time taken: 34 mins 45 secs

Question: 20 of 100

A patient with type 2 diabetes being treated with gliclazide presents with sweating and dizziness.

He is on treatment for hypertension, atrial fibrillation, joint pain and indigestion.

Blood glucose was 1.9 mmol/L (3.0-6.0).

Which of the following drugs is responsible?

(Please select 1 option)

○	Aspirin
○	Atenolol
○	Digoxin
○	Fluconazole
○	Ranitidine

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

○	Fluconazole ← This is the correct answer
◉	Ranitidine ✕ Incorrect answer selected

Gliclazide is highly bound to plasma proteins, about 94%. Its free plasma level increases on displacement by aspirin given for joint pains.

As a result of drug interaction hypoglycaemia may be potentiated when a sulfonylurea is used concurrently with agents such as

- Long-acting sulfonamides
- Tuberculostatics
- Phenylbutazone
- Clofibrate
- Monoamine oxidase (MAO) inhibitors
- Coumarin derivatives
- Salicylates
- Probenecid
- Propranolol
- Cimetidine
- Disopyramide
- Angiotensin converting enzyme inhibitors.

Plasma protein binding of fluconazole is low and its excreted by kidney.

Gliclazide is a sulphonylurea drug with an intermediate half life of around 11 hours. It is extensively metabolised within the liver by CYP2C9.

Renal clearance accounts for only 4% of total drug clearance.

- Long-acting sulfonamides
- Tuberculostatics
- Phenylbutazone
- Clofibrate
- Monoamine oxidase (MAO) inhibitors
- Coumarin derivatives
- Salicylates
- Probenecid
- Propranolol
- Cimetidine
- Disopyramide
- Angiotensin converting enzyme inhibitors.

Plasma protein binding of fluconazole is low and its excreted by kidney.

Gliclazide is a sulphonylurea drug with an intermediate half life of around 11 hours. It is extensively metabolised within the liver by CYP2C9.

Renal clearance accounts for only 4% of total drug clearance.

As fluconazole is a potent inhibitor of CYP2C8 and CYP2C9 it may also interact with the sulphonylureas (for example, glimepiride and gliclazide).

Thus the best answer in this scenario would be likely to be fluconazole.

Question: 21 of 100

A 52-year-old schoolteacher attends with weight loss and sweats.

She is clinically thyrotoxic with a diffuse goitre.

Subsequent investigations show:

Free T4	40 pmol/l	(9-23)
Free T3	9.8 nmol/l	(3.5-6)
TSH	6.1 mU/l	(0.5-5)

A repeat TFT is similar.

What is the most appropriate investigation for this patient?

(Please select 1 option)

- FNA of thyroid gland
- MRI scan pituitary gland
- Radio-isotope uptake scan of thyroid gland
- Repeat TFT checking for antibody interference
- Thyroid auto antibodies

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Subsequent investigations show:

Free T4	40 pmol/l	(9-23)
Free T3	9.8 nmol/l	(3.5-6)
TSH	6.1 mU/l	(0.5-5)

A repeat TFT is similar.

What is the most appropriate investigation for this patient?

(Please select 1 option)

- ○ FNA of thyroid gland
- ◉ MRI scan pituitary gland ✓ Correct
- ○ Radio-isotope uptake scan of thyroid gland
- ○ Repeat TFT checking for antibody interference
- ○ Thyroid auto antibodies

This patient is thyrotoxic; however, as the non-suppressed thyroid-stimulating hormone (TSH) suggests that this is due to excessive TSH production by the pituitary gland, the possibility of a thyrotroph adenoma must be pursued.

In primary hyperthyroidism the TSH should always be suppressed by negative feedback, which is not the case here.

TSH-omas are indeed very rare, but the giveaway would be the normal or elevated TSH with thyrotoxicosis.

Work Smart Session - MRCP Part 1

Time taken: 38 mins 20 secs

Question: 22 of 100

In a study healthy volunteers are given 50 mls of 50% dextrose solution by one of two routes. Route A is intravenous and Route B is via a nasogastric tube.

Every 15 minutes the plasma insulin level and glucose are measured and plotted on a graph.

Which of the following statements would best describe the likely results comparing Route A to Route B in this experiment?

(Please select 1 option)

- Insulin and glucose the same in Route A and Route B
- Insulin higher, glucose higher in Route A
- Insulin higher, glucose higher in Route B
- Insulin higher, glucose lower in Route A
- Insulin higher, glucose lower in Route B

Submit answer | Skip question | Remove Tag | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

(Please select 1 option)

○	Insulin and glucose the same in Route A and Route B
○	Insulin higher, glucose higher in Route A
○	Insulin higher, glucose higher in Route B
○	Insulin higher, glucose lower in Route A
◉	Insulin higher, glucose lower in Route B ✓ Correct

Glucose given via the gut elicits a greater insulin response as compared to the same quantity given intravenously even though the plasma glucose peak is higher when it is given IV. This phenomenon is called the 'incretin effect'.

The incretin effect denominates the phenomenon that oral glucose elicits a higher insulin response than does intravenous glucose.

The two hormones responsible for the incretin effect, glucose-dependent insulinotropic hormone (GIP) and glucagon-like peptide-1 (GLP-1), are secreted after oral glucose loads and augment insulin secretion in response to hyperglycaemia.

Gastric Inhibitory Polypeptide and Glucagon-Like Peptide-1 in the Pathogenesis of Type 2 Diabetes. Diabetes 53:S190-S196, 2004

The investigation of the incretin effect is not usually performed using the same quantity of glucose as in this question. An 'isoglycaemic study' is often used where an infusion of glucose is designed to copy exactly the blood glucose profile generated in an individual or animal by a certain enteral glucose load.

Exenatide (synthetic exendin-4) is a new agent for the treatment of type 2 diabetes. Exendin-4 occurs naturally in the saliva venom of the North American lizard called the Gila Monster. It mimics the action of the gut hormone GLP-1 (Glucagon-like peptide 1).

Work Smart Session - MRCP Part 1

Time taken: 40 mins 29 secs

Question: 23 of 100

A 54-year-old male who is a HGV driver and has a 10 year history of type 2 diabetes is seen on annual review.

His glycaemic control is poor with a HBA1c of 10.5% on maximal oral hypoglycaemic therapy (3.8-6.4).

You suggest switching to insulin but he refuses to do this as he would lose his HGV licence. He also refuses to inform the DVLA himself.

What is the most appropriate action in this case?

(Please select 1 option)

- Continue to review patient in clinic and accept that he continues to drive
- Discharge him from clinic as there is nothing more that you can do
- Inform his employer that he must stop driving and suggest administrative work
- Inform the DVLA even if the patient withholds his consent
- Tell his next of kin that they should inform the DVLA that he is nol onger fit to drive

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

His glycaemic control is poor with a HBA1c of 10.5% on maximal oral hypoglycaemic therapy (3.8-6.4).

You suggest switching to insulin but he refuses to do this as he would lose his HGV licence. He also refuses to inform the DVLA himself.

What is the most appropriate action in this case?

(Please select 1 option)

◉	Continue to review patient in clinic and accept that he continues to drive ✓ Correct
○	Discharge him from clinic as there is nothing more that you can do
○	Inform his employer that he must stop driving and suggest administrative work
○	Inform the DVLA even if the patient withholds his consent
○	Tell his next of kin that they should inform the DVLA that he is nol onger fit to drive

In this particular case, the patient has poor glycaemic control, but otherwise has no features whatsoever that preclude him from driving such as retinopathy, neuropathy or hypoglycaemic episodes.

You cannot therefore force this patient to switch to insulin and neither can you stop him driving.

He will continue to need a regular medical every three years for his continued HGV licence.

Work Smart Session - MRCP Part 1

Time taken: 42 mins 53 secs

Question: 24 of 100

A 33-year-old female presents with a one year history of galactorrhoea and amenorrhoea. She informs you that she does not want to become pregnant. On examination there is galactorrhoea to expression and visual fields are normal to confrontation.

Investigations confirm the diagnosis of a macroprolactinoma, with a prolactin concentration of 10,500 mu/l (50-500) and MRI of the pituitary revealing a 1.5 cm tumour with some suprasellar extension.

What is the most appropriate treatment for this woman?

(Please select 1 option)

- Cabergoline therapy
- Combined oral contraceptive
- Pituitary surgery
- Somatostatin analogue therapy
- Stereotactic pituitary irradiation

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

pituitary revealing a 1.5 cm tumour with some suprasellar extension.

What is the most appropriate treatment for this woman?

(Please select 1 option)

◉	Cabergoline therapy ✓ Correct
○	Combined oral contraceptive
○	Pituitary surgery
○	Somatostatin analogue therapy
○	Stereotactic pituitary irradiation

This young woman has a macroprolactinoma and these are exquisitely sensitive to dopamine agonist therapy and rapid tumour reduction with restoration of menses and cessation of galactorrhoea expected.

Pituitary surgery is rarely required in prolactinomas and is generally reserved for patients intolerant or resistant to dopamine agonist therapy.

Even with large tumours that compress the chiasm, these can be treated with dopamine agonists with rapid reduction in size and relief of pressure.

The fact that she does not want to become pregnant is a bit of an irrelevance. One would still treat her with dopamine agonist therapy and suggest use of appropriate contraception which could include the OCP.

Next question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 28-year-old female is referred with a three month history of tiredness and weakness.

On examination, pulse is 82 bpm and blood pressure is 128/72 mmHg. No specific abnormalities are evident on examination of the cardiovascular, respiratory, abdominal or neurological systems.

Investigations reveal:

Serum sodium	142 mmol/l	(137-144)
Serum potassium	3.0 mmol/l	(3.5-4.9)
Serum urea	4.2 mmol/l	(2.5-7.5)
Serum creatinine	82 µmol/l	(60-110)
Serum chloride	73 mmol/l	(95-107)
Plasma glucose	5.5 mmol/l	(3.0-6.0)
Urinary chloride	60 mmol/l	(20-350)

Which of the following is the likely diagnosis?

(Please select 1 option)

- Bartter's syndrome
- Conn's syndrome
- Drug ingestion
- Liddle's syndrome
- Non-classical congenital adrenal hyperplasia (CAH)

(Please select 1 option)

◉	Bartter's syndrome ✗ Incorrect answer selected
○	Conn's syndrome
○	Drug ingestion ← This is the correct answer
○	Liddle's syndrome
○	Non-classical congenital adrenal hyperplasia (CAH)

This young woman has hypokalaemia and hypochloraemia.

The normal blood pressure would exclude a diagnosis of Conn's, CAH, or Liddle's syndrome (apparent mineralocorticoid excess). Similarly, drug ingestion associated with hypokalaemia liquorice/carbenoxolone is associated with hypertension (and low urinary chloride less than 20 mmol/l).

Bartter's syndrome is a rare, recessive condition associated with weakness, lethargy and growth retardation and is found in youngsters. Hypokalaemic hypochloraemic alkalosis is seen in the condition but symptoms would be more apparent at a much younger age than this woman.

If Gitelman's syndrome were offered then that would be a better option.

Therefore the most likely diagnosis as the symptoms have arisen only over the last three months and no other features are apparent on examination, is diuretic abuse.

Work Smart Session - MRCP Part 1

Question: 26 of 100

A 19-year-old male presents with concerns regarding his pubertal development.

On examination he is 1.8 m tall, thin and has little pubic and axillary hair. Both testes are approximately 5 ml in volume (NR 15 ml). No other abnormalities are encountered.

Investigations reveal:

LH	3.3 mU/l	(3-10)
FSH	5.5 mU/l	(3-10)
Testosterone	5.5 nmol/l	(9-30)

Which of the following is the most likely diagnosis?

(Please select 1 option)

- Anorexia nervosa
- Craniopharyngioma
- Kallmann's syndrome
- Klinefelter's syndrome
- Primary testicular failure

Submit answer | Skip question | Tag Question | Remove question

(Please select 1 option)

○	Anorexia nervosa
○	Craniopharyngioma
○	Kallmann's syndrome ← This is the correct answer
◉	Klinefelter's syndrome ✕ Incorrect answer selected
○	Primary testicular failure

This young male has delayed puberty with hypogonadotrophic hypogonadism. The most likely explanation would be Kallmann's syndrome.

Klinefelter's would be associated with elevated luteinising hormone/follicle stimulating hormone (LH/FSH), as would primary testicular failure.

His height of 1.8 m, suggesting that he is tall, would argue against this being anorexia despite his thin appearance. If anorexia had preceded puberty then his stature should also have been affected.

The only other possibility is craniopharyngioma, but this is probably less likely in an otherwise well man, and other possible features should be included to suggest this diagnosis, for example, visual fields.

You may wish to cry foul at this point, and say that anosmia should be given as a clue to Kallmann's; however, in reality how often do you ask about sense of smell, let alone test for it?!

Work Smart Session - MRCP Part 1

Question: 27 of 100

A 24-year-old female presents with a two week history of polyuria and polydipsia together with frequent nocturia.

Investigations show

Serum sodium	144 mmol/L (137-144)
Serum potassium	3.3 mmol/L (3.5-4.9)
Serum calcium	2.6 mmol/L (2.2-2.6)
Plasma glucose	6.8 mmol/L (3.0-6.0)
Serum osmolality	310 mOsmol/L (275-295)

What is the diagnosis?

(Please select 1 option)

- Diabetes insipidus
- Diabetes mellitus
- Drug abuse
- Primary hyperparathyroidism
- Primary polydipsia

Submit answer | Skip question | Tag Question | Remove question

- Shop

Plasma glucose	6.8 mmol/L (3.0-6.0)
Serum osmolality	310 mOsmol/L (275-295)

What is the diagnosis?

(Please select 1 option)

◉	Diabetes insipidus ✕ Incorrect answer selected
○	Diabetes mellitus
○	Drug abuse ← This is the correct answer
○	Primary hyperparathyroidism
○	Primary polydipsia

This patient has polyuria and polydipsia of relatively recent onset and has an elevated plasma osmolality with a high calcium and glucose concentration.

These features would be unlikely in DI and are more in keeping with thiazide diuretic abuse - high calcium, glucose and hypokalaemia.

Similarly, the serum osmolality would be low in association with primary polydipsia.

There may be plenty of variations purely by alteration of the biochemistry of this question in the examination.

Work Smart Session - MRCP Part 1

Question: 28 of 100

A 25-year-old female presents with weight gain, oligomenorrhoea and primary infertility. She has a history of bipolar disorder for which she takes lithium.

On examination she has a BMI of 32 kg/m^2.

Investigations reveal:

Free T4	6.4 pmol/l	(10-22)
TSH	42 mU/l	(0.4-5)
Prolactin	980 mU/l	(50-450)

What is the most appropriate treatment for this patient?

(Please select 1 option)

- Cabergoline
- Cabergoline plus thyroxine
- Metformin
- Stop lithium
- Thyroxine

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

(Please select 1 option)

○	Cabergoline
○	Cabergoline plus thyroxine
○	Metformin
○	Stop lithium
◉	Thyroxine ✓ Correct

This patient has primary hypothyroidism which would explain the increasing weight and the associated hyperprolactinaemia.

The latter occurs as a consequence of reduced dopaminergic tone.

Lithium may be the cause of this but stopping it is not usually attempted since it may dangerously exacerbate the psychiatric illness. There is an excellent review by John Lazarus on this topic[1] where he says, "The common clinical side effects of the drug are goitre in up to 40% and hypothyroidism in about 20%. Lithium increases thyroid autoimmunity if present before therapy. Treatment with levothyroxine is effective and lithium therapy should not be stopped."

The most appropriate treatment for her would be thyroxine which would, through euthyroidism, be expected to normalise prolactin concentration.

In turn this may improve weight, menstrual function and fertility.

Work Smart Session - MRCP Part 1

Time taken: 54 mins 46 secs

Question: 29 of 100

A 65-year-old male undergoes a CT headscan after falling from a ladder and knocking himself out.

The CT report reveals that he has a 1.3 cm macroadenoma which does not encroach upon the optic chiasm. On recovery he is perfectly well and examination is entirely normal, including full viusal fields to confrontation.

Investigations reveal normal thyroid function, testosterone concentration and short Synacthen test results. His prolactin concentration is 550 mU/L (50-450).

What is the most appropriate treatment for this patient?

(Please select 1 option)

- Advise trans-sphenoidal hypophysectomy
- Arrange pituitary radiotherapy
- Arrange serial imaging
- No further investigation/treatment required
- Treat with cabergoline

Submit answer | Skip question | Tag Question | Remove question

perfectly well and examination is entirely normal, including full viusal fields to confrontation.

Investigations reveal normal thyroid function, testosterone concentration and short Synacthen test results. His prolactin concentration is 550 mU/L (50-450).

What is the most appropriate treatment for this patient?

(Please select 1 option)

○	Advise trans-sphenoidal hypophysectomy
○	Arrange pituitary radiotherapy
○	Arrange serial imaging ← This is the correct answer
○	No further investigation/treatment required
◉	Treat with cabergoline ✕ Incorrect answer selected

This man has a co-incidentally detected pituitary macroadenoma.

The small elevation in prolactin probably reflects stalk compression and does not indicate that this is a prolactinoma. In macroprolactinomas, the prolactin concentration is greater than 2000 mU/L.

In this man's case, with no visual field defects and the tumour being distant from the chiasm, the most appropriate treatment would be observation with serial scanning to assess for any change in size that would then merit surgical intervention.

However, this man who is eupituitary may never encounter any growth in this co-incidentally detected non-functional pituitary tumour.

Which of the following drugs on her prescription is likely to have been responsible?

(Please select 1 option)

○	Aspirin
○	Augmentin
○	Oramorph
○	Paracetamol
◉	Sodium valproate ✓ Correct

AIP is an autosomal dominant disease resulting from defects in production or activity of the enzyme porphobilinogen (PBG) deaminase.

Attacks may be precipitated by fasting, and by many drugs, such as

- Phenobarbitone
- Alcohol
- Sulphonylureas
- Oestrogens.

Amoxicillin and opiates are thought to be safe in porphyria.

Work Smart Session - MRCP Part 1

Question: 3 of 100

A 25-year-old is admitted on the medical intake. She is ten weeks post partum and has been generally unwell for two weeks with malaise sweats and anxiety.

On examination she is haemodynamically stable and clinically euthyroid.

TFTs show the following:

Free T4	33 pmol/l	(9-23)
Free T3	8 nmol/l	(3.5-6)
TSH	<0.02 mU/l	(0.5-5)

What is the appropriate management?

(Please select 1 option)

- Carbimazole 40 mg/day
- Lugol's iodine
- Propranolol 20 mg tds
- Propylthiouracil 50 mg/tds
- Radioactive iodine therapy

Question: 30 of 100

Which of the following statements is correct concerning the relationship between type 2 diabetes and colonic cancer?

(Please select 1 option)

◉	Increased concentrations of C-peptide are a marker of increased colorectal cancer risk
○	Insulin treatment increases recurrence free survival after treatment of colonic cancer
○	The increased risk of colorectal cancer in diabetes is related to BMI
○	The increased risk of colorectal cancer in diabetes is related to total cholesterol
○	Type 1 diabetes has similar risks of colonic cancer as does type 2 diabetes

Work Smart Session - MRCP Part 1

Time taken: 57 mins 3 secs

Question: 30 of 100

Which of the following statements is correct concerning the relationship between type 2 diabetes and colonic cancer?

(Please select 1 option)

◉	Increased concentrations of C-peptide are a marker of increased colorectal cancer risk ✓ Correct
○	Insulin treatment increases recurrence free survival after treatment of colonic cancer
○	The increased risk of colorectal cancer in diabetes is related to BMI
○	The increased risk of colorectal cancer in diabetes is related to total cholesterol
○	Type 1 diabetes has similar risks of colonic cancer as does type 2 diabetes

Type 2 diabetes is associated with a 40-60% increase in the risk of cancer of the large bowel. This increase is linked to changes in HbA1c.

Type 2 diabetes is associated with significantly higher rates of overall mortality and reduced disease free and recurrence free survivals after chemotherapy/radiotherapy, and insulin has not been shown to have any effects on mortality.

No association has been found between colonic malignancy and type 1 diabetes, nor gestational diabetes.

For a discussion see BMJ 2005;330:551-2.

Question: 31 of 100

A 26-year-old female with no previous history of diabetes presents with a first episode of diabetic ketoacidosis. There is no evidence of infection but she has recently commenced a new medication.

Which of the following drugs is implicated in precipitating diabetic ketoacidosis?

(Please select 1 option)

○	Olanzapine ← This is the correct answer
○	Omeprazole
◉	Progestogen only contraceptive pill ✕ Incorrect answer selected
○	Sodium valproate
○	Venlafaxine

The atypical antipsychotics such as olanzapine have been implicated in precipitating diabetes as well as diabetic ketoacidosis.

Other drugs implicated include thiazide diuretics, beta sympathomimetics and steroids.

Question: 33 of 100

Which of the following percentages most accurately reflects the mortality associated with the modern management of diabetic ketoacidosis?

(Please select 1 option)

○	0.5%
○	1%
◉	2-3% ✓ Correct
○	5-6%
○	8-10%

Despite the advances in the management of diabetes in general and the improvements in intensive care, studies reveal that the mortality associated with diabetic ketoacidosis remains stubbornly around the 2-5% since the 1970s.

Specifically, mortality relates to cerebral oedema.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 51 secs

Question: 34 of 100

A 30-year-old female who is 24 weeks pregnant presents with a blood pressure on three separate occasions of approximately 160/110 mmHg.

Her liver function tests (LFTs) show:

Aspartate transaminase	150 U/l	(5-45)
Alkaline phosphatase	213 U/l	(50-120)
Bilirubin	31 µmol/l	(0-18)

Which antihypertensive is indicated?

(Please select 1 option)

- Atenolol
- Irbesartan
- Labetalol
- Methyldopa
- Ramipril

Submit answer | Skip question | Tag Question | Remove question

Her liver function tests (LFTs) show:

Aspartate transaminase	150 U/l	(5-45)
Alkaline phosphatase	213 U/l	(50-120)
Bilirubin	31 µmol/l	(0-18)

Which antihypertensive is indicated?

(Please select 1 option)

- (●) Atenolol ✗ Incorrect answer selected
- ( ) Irbesartan
- ( ) Labetalol ← This is the correct answer
- ( ) Methyldopa
- ( ) Ramipril

Angiotensin-converting enzyme inhibitors are contraindicated in pregnancy as they cause renal dysgenesis in the fetus. For this reason A2RBs are also not recommended for use in pregnancy.

There is a theoretical risk of intrauterine growth retardation with the use of atenolol in pregnancy although the studies which showed this effect were done with very large doses of atenolol.

One would not utilise methyldopa in a patient with abnormal LFTs.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 3 mins 21 secs

Question: 35 of 100

A 25-year-old nurse presents with fatigue, tremulousness and a 7 kg weight loss over the past one month. On examination she has a tachycardia but no other abnormal findings.

Thyroid function tests show:

Free thyroxine	40 pmol/L (10-23)
TSH	<0.01 mU/L (0.5-5.0)

Which one of the following would confirm the diagnosis of thyroiditis?

(Please select 1 option)

- Elevated free T3 concentration
- Failure of TSH to rise following IV TRH
- High titre of thyroid peroxidase antibodies
- Negligible four hour radioiodine thyroid uptake
- Raised ESR

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Thyroid function tests show:

Free thyroxine	40 pmol/L (10-23)
TSH	<0.01 mU/L (0.5-5.0)

Which one of the following would confirm the diagnosis of thyroiditis?

(Please select 1 option)

- Elevated free T3 concentration
- Failure of TSH to rise following IV TRH
- High titre of thyroid peroxidase antibodies
- Negligible four hour radioiodine thyroid uptake ← This is the correct answer
- Raised ESR ✕ Incorrect answer selected

This test result and symptoms may be consistent with thyroiditis such as DeQuervain's and an elevated ESR with negligible uptake of RAI (as thyroid cells are attacked and hence release stored T4 but fail to synthesise T4) would be expected.

In Graves' disease you would expect homogenous uptake whereas a toxic nodule would show a solitary area of high uptake.

Antibodies such as TPO, and TSH receptor antibodies are found in autoimmune thyroid disease.

The TRH test is seldom used except in thyroid oncology.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 5 mins 16 secs

Question: 36 of 100

A 32-year-old male with type 1 diabetes undergoes a 24 hour urine collection.

Which of the following urine albumin concentrations signify microalbuminuria?

(Please select 1 option)

○	10 mg/day
○	50 mg/day
○	500 mg/day
○	1 g/day
○	3.5 g/day

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

A 32-year-old male with type 1 diabetes undergoes a 24 hour urine collection.

Which of the following urine albumin concentrations signify microalbuminuria?

(Please select 1 option)

○	10 mg/day
◉	50 mg/day ✓ Correct
○	500 mg/day
○	1 g/day
○	3.5 g/day

Microalbuminuria is defined as a urine albumin excretion of between 30-300 mg per 24 hours.

A concentration above 300 mg/24 hours signifies albuminuria and a concentration above 3.5 g/24 hours signifies overt proteinuria.

Microalbuminuria is not just an indictor of early renal involvement but it also identifies increased cardiovascular risk with an approximate two- fold cardiovascular risk above the already increased risk in the diabetic population.

A useful surrogate of the total albumin excretion is the albumin: creatinine ratio. The urinary albumin:creatinine ratio is measured using the first morning urine sample where practicable.

Microalbuminuria is indicated where there is an albumin:creatinine ratio ≥2.5 mg/mmol (men) or 3.5 mg/mmol (women).

Proteinuria is indicated by a ratio of ≥30 mg/mmol.

Question: 37 of 100

A 43-year-old male is diagnosed with diabetic nephropathy. If this patient had type 1 diabetes his chances of progressing to end stage renal disease (ESRD) would be approximately 50%.

What percentage of patients with type 2 diabetes with diabetic nephropathy would be expected to progress to ESRD?

(Please select 1 option)

○	15% ← This is the correct answer
○	30%
○	45%
○	50%
◉	55% ✕ Incorrect answer selected

Although the incidence of diabetic nephropathy is less in type 2 diabetics as approximately 90-95% of all diabetics are type 2s, the majority of patients with diabetic nephropathy are type 2 diabetics.

There are a number of stages in the development of nephropathy with glomerular hyperfiltration being an early feature. Nephropathy itself is signalled by the excretion of trace amounts of protein in the urine microalbuminuria.

The progression of the disease may be attenuated by stringent blood pressure control (with an angiotensin-converting enzyme inhibitor [ACEi]) and strict glycaemic control.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 7 mins 41 secs

Question: 38 of 100

A 62-year-old female with a six year history of type 2 diabetes attends for annual review. Her HbA1c is 10% (3.8-6.4).

Into what average plasma glucose concentration does her HbA1c translate?

(Please select 1 option)

- 7.5 mmol/l
- 10 mmol/l
- 12.5 mmol/l
- 15.5 mmol/l
- 19 mmol/l

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

(Please select 1 option)

○	7.5 mmol/l
○	10 mmol/l
◉	12.5 mmol/l ✗ Incorrect answer selected
○	15.5 mmol/l ← This is the correct answer
○	19 mmol/l

The HbA1c is an important reflection of control over a three month period (life expectancy of the erythrocyte).

There is a good relationship between the rise in glucose and its ability to glycosylate the Hb molecule (there is a difference between average plasma glucose and blood glucose).

Thus a HbA1c of 7% would translate into an average **plasma** (higher than value of **blood** glucose) glucose of 9.5 mmol/l and a HbA1c of 10% into 15.5 mmol/l.

This is the reason why so much emphasis is placed on controlling HbA1c rather than the specific glucose measurements, as these vary so much throughout the day.

This is a difficult question and it is very unlikely that you would be asked to translate average blood glucose into an exact HbA1c figure; however it is useful to realise that the numerical values are not the same.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 9 mins 19 secs

Question: 39 of 100

An 18-year-old woman presented with a history of 15 kg weight loss in the previous four months. She has been amenorrheic for some months.

On examination she had fine lanugo hair and a blood pressure of 110/60 mmHg.

Which one of the following laboratory results would support the most likely clinical diagnosis?

(Please select 1 option)

- ○ High plasma follicle stimulating hormone (FSH) concentration
- ○ Low plasma testosterone concentration
- ○ High serum ferritin concentration
- ○ Low plasma cortisol concentration
- ○ Suppressed thyroid stimulating hormone (TSH) concentration

Submit answer | Skip question | Remove Tag | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

some months.

On examination she had fine lanugo hair and a blood pressure of 110/60 mmHg.

Which one of the following laboratory results would support the most likely clinical diagnosis?

(Please select 1 option)

○	High plasma follicle stimulating hormone (FSH) concentration
○	Low plasma testosterone concentration
○	High serum ferritin concentration
○	Low plasma cortisol concentration
◉	Suppressed thyroid stimulating hormone (TSH) concentration ✓ Correct

The question alludes to a patient with anorexia nervosa.

Anorexia is associated with functional hypogonadotrophic hypogonadism with low FSH and luteinising hormone (LH) levels.

Cortisol levels may be increased but are typically within the 'normal range'. They may however, may fail to suppress with dexamethasone.

Plasma testosterone levels are normal in females with anorexia.

Basal levels of TSH may be depressed in anorexia, though T4 and T3 may be normal.

Ferritin levels are low in a state of malnutrition.

TSH	<0.02 mU/l	(0.5-5)

What is the appropriate management?

(Please select 1 option)

- Carbimazole 40 mg/day
- Lugol's iodine
- Propranolol 20 mg tds ✓ Correct
- Propylthiouracil 50 mg/tds
- Radioactive iodine therapy

The diagnosis here is likely to be post partum thyroiditis which tends to occur within the three months of delivery, followed by a hypothyroid phase at three to six months, followed by spontaneous recovery in one third of cases.

In the remaining two-thirds a single-phase pattern or the reverse occurs.

Management is centred on symptomatic treatment using beta-blockers for relief of tremor or anxiety, and observation for the development of persistent hypo- or hyperthyroidism.

Work Smart Session - MRCP Part 1

Time taken: 5 mins 18 secs

Question: 4 of 100

A 70-year-old woman is referred by her GP with a breast lump.

She was asymptomatic but her investigations reveal:

Corrected calcium	2.72 mmol/L (2.2-2.6)
Phosphate	0.80 mmol/L (0.8-1.4)
Alkaline phosphatase	110 U/L (45-105)
PTH concentration	5.1 pmol/L (0.9-5.4)

What is the most likely diagnosis?

(Please select 1 option)

- Bony metastases
- Chronic vitamin D excess
- Ectopic PTH related peptide (PTHrp) secretion
- Multiple myeloma
- Primary hyperparathyroidism

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Question: 40 of 100

A 73-year-old woman presented with thirst and polyuria of six months duration.

She had suffered several episodes of lower back pain. She was on no medication. On examination she looked well, had a dorsal kyphosis and a blood pressure of 170/95 mmHg.

Investigations revealed:

Erythrocyte sedimentation rate	15 mm/1st hour (0-30)
Serum urea	11.9 mmol/L (2.5-7.5)
Serum creatinine	175 µmol/L (60-110)
Serum albumin	40 g/L (37-49)
Serum total calcium	2.98 mmol/L (2.2-2.6)

What is the most likely cause of this lady's hypercalcaemia?

(Please select 1 option)

- Metastatic breast cancer
- Myeloma
- Osteoporosis
- Primary hyperparathyroidism
- Sarcoidosis

Submit answer | Skip question | Tag Question | Remove question

Serum total calcium	2.98 mmol/L (2.2-2.6)

What is the most likely cause of this lady's hypercalcaemia?

(Please select 1 option)

- Metastatic breast cancer
- Myeloma
- Osteoporosis
- Primary hyperparathyroidism ✓ Correct
- Sarcoidosis

The prevalence of hyperparathyroidism is said to be four per 1000 in women over 60, and is two to three times more common in women than men.

The lower back pain may be loin pain due to renal colic caused by renal calculi or due to osteoporosis. The renal impairment may be associated with renal calculi, perhaps due to calculi-induced hydronephrosis in extreme cases. Renal impairment in hyperparathyroidism is not uncommon. Chronic hypercalcaemia can compromise the renal concentrating ability leading to polydipsia and polyuria.

The kyphosis may be due to osteoporosis which is commonly seen in conjunction with hyperparathyroidism. Classically, hypertension has been associated with hyperparathyroidism.

Associated with myeloma one would expect a drop in albumin concentration together with a markedly elevated ESR.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 21 mins 56 secs

Question: 41 of 100

A 40-year-old man is undergoing investigation for acromegaly.

MRI of the pituitary fossa is normal, but a routine chest x ray reveals a large centrally based mass. The patient is a non-smoker.

What is the most likely type of this lung tumour?

(Please select 1 option)

○	Adenocarcinoma
○	Carcinoid ← This is the correct answer
○	Large cell
◉	Small cell ✕ Incorrect answer selected
○	Squamous cell

A central based mass in a non-smoker showing clinical evidence of neuroendocrine cell origin is consistent with a carcinoid and surgery offers a very high chance of cure.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 21 mins 56 secs

Question: 42 of 100

Which of the following hormones acts through cyclic AMP as the second messenger?

(Please select 1 option)

- Insulin
- Oestradiol
- PTH
- TRH
- Triiodothyronine

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

◉	PTH ✓ Correct
○	TRH
○	Triiodothyronine

Unlike steroids (progesterone, testosterone, oestradiol and cortisol) other ionic hormones such as:

- Adrenaline
- Growth hormone-releasing hormone (GHRH)
- Glucagon
- Luteinising hormone (LH)
- Follicle stimulating hormone (FSH)
- Parathyroid hormone (PTH)
- Thyroid-stimulating hormone (TSH)

are unable to pass the plasma membrane acting upon cell surface receptors and then through cyclic adenosine monophosphate (cAMP) as the second messenger.

Insulin acts through mitogen-activated protein (MAP) kinase pathway, as does growth hormone (GH) and prolactin.

- Thyroid releasing hormone (TRH)
- Gonadatrophin-releasing hormone (GnRH)
- Antidiuretic hormone (ADH)

act through calcium/phosphoinositide.

Nitric oxide and atrial natriuretic peptide (ANP) act through cyclic guanosine monophosphate (cGMP).

Triiodothyronine (T3) acts by binding to intracellular receptors.

Unlike steroids (progesterone, testosterone, oestradiol and cortisol) other ionic hormones such as:

- Adrenaline
- Growth hormone-releasing hormone (GHRH)
- Glucagon
- Luteinising hormone (LH)
- Follicle stimulating hormone (FSH)
- Parathyroid hormone (PTH)
- Thyroid-stimulating hormone (TSH)

are unable to pass the plasma membrane acting upon cell surface receptors and then through cyclic adenosine monophosphate (cAMP) as the second messenger.

Insulin acts through mitogen-activated protein (MAP) kinase pathway, as does growth hormone (GH) and prolactin.

- Thyroid releasing hormone (TRH)
- Gonadatrophin-releasing hormone (GnRH)
- Antidiuretic hormone (ADH)

act through calcium/phosphoinositide.

Nitric oxide and atrial natriuretic peptide (ANP) act through cyclic guanosine monophosphate (cGMP).

Triiodothyronine (T3) acts by binding to intracellular receptors.

Question: 43 of 100

A 60-year-old man is admitted with a productive cough with flecks of blood in his sputum.

Chest x ray reveals a mass lesion in the right mid zone.

Investigations reveal:

Sodium	110 mmol/L (137-144)
Potassium	4.0 mmol/L (3.5-4.9)
Bicarbonate	24 mmol/L (20-28)
Urea	3.0 mmol/L (2.5-7.5)
Creatinine	80 µmol/L (60-110)

Which of the following findings suggest a diagnosis of the syndrome of inappropriate ADH (SIADH) secretion?

(Please select 1 option)

- ○ Plasma osmolality 236 mosmol/kg (278-305)
- ○ Presence of ascites
- ○ Urine flow rate 20 mL/hour
- ○ Urine osmolality 250 mosmol/kg (350-1000)
- ○ Urine sodium 110 mmol/L

EN 7:36 PM 2/21/2011

Sodium	110 mmol/L (137-144)
Potassium	4.0 mmol/L (3.5-4.9)
Bicarbonate	24 mmol/L (20-28)
Urea	3.0 mmol/L (2.5-7.5)
Creatinine	80 µmol/L (60-110)

Which of the following findings suggest a diagnosis of the syndrome of inappropriate ADH (SIADH) secretion?

(Please select 1 option)

- ○ Plasma osmolality 236 mosmol/kg (278-305)
- ○ Presence of ascites
- ○ Urine flow rate 20 mL/hour
- ◉ Urine osmolality 250 mosmol/kg (350-1000) ✕ Incorrect answer selected
- ○ Urine sodium 110 mmol/L ← This is the correct answer

The serum osmolality associated with hyponatraemia is generally low and so would not in itself suggest SIADH.

However, in the context of the low plasma osmolality a high urine osmolality (2x that of the plasma osmolality) with an elevated urine sodium (above 20 mmol/L) is suggestive of this diagnosis.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 25 mins 4 secs

Question: 44 of 100

A 23-year-old woman with type 1 diabetes (T1DM) of three years duration, presents for annual review with weight loss.

She had normal menstrual cycles and bowel habit was unchanged.

On examination her BMI was 23 kg/m^2 and investigations revealed a haemoglobin of 7 g/dL (11.5-16.5) and a MCV of 69 fL (80-96).

Which of the following is the most likely diagnosis?

(Please select 1 option)

- Anorexia nervosa
- Bacterial overgrowth
- Beta-thalassaemia minor
- Coeliac disease
- Crohn's disease

Question: 44 of 100

A 23-year-old woman with type 1 diabetes (T1DM) of three years duration, presents for annual review with weight loss.

She had normal menstrual cycles and bowel habit was unchanged.

On examination her BMI was 23 kg/m^2 and investigations revealed a haemoglobin of 7 g/dL (11.5-16.5) and a MCV of 69 fL (80-96).

Which of the following is the most likely diagnosis?

(Please select 1 option)

○	Anorexia nervosa
○	Bacterial overgrowth
○	Beta-thalassaemia minor
◉	Coeliac disease ✓ Correct
○	Crohn's disease

Coeliac disease is the likely option as this patient has autoimmune disease (T1DM), an iron deficiency anaemia and little in the way of symptoms.

Bacterial overgrowth is associated with profuse diarrhoea and a macrocytosis due to vitamin B12 consumption.

Crohn's disease again would be expected to be symptomatic.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 26 mins 24 secs

Question: 45 of 100

A 47-year-old schoolteacher presents to her GP with fatigue.

The GP noted her to be hypercalcaemic with an albumin of 39 g/L (37-49), globulin of 28g/L and Ca^{++} of 2.80 mmol/l (2.2-2.6).

Which of the following statements is true?

(Please select 1 option)

○	24 hour urinary calcium assay is of no use at all.
○	Modern assays for PTH and PTHrp may cross-react so assays are unreliable.
○	Primary hyperparathyroidism will be diagnosed only if the PTH is at least three times the normal range.
○	The most likely diagnosis is myeloma.
○	The patient could have surgery if renal stones are found on ultrasound

Submit answer | Skip question | Tag Question | Remove question

Which of the following statements is true?

(Please select 1 option)

○	24 hour urinary calcium assay is of no use at all.
○	Modern assays for PTH and PTHrp may cross-react so assays are unreliable.
○	Primary hyperparathyroidism will be diagnosed only if the PTH is at least three times the normal range.
○	The most likely diagnosis is myeloma.
◉	The patient could have surgery if renal stones are found on ultrasound ✓ Correct

Twenty four hour urinary calcium may be useful if used in comparison to the serum calcium in order to distinguish familial hypocalciuric hypercalcaemia from primary hyperparathyroidism.

Parathyroid hormone (PTH) may be less than twice the upper limit of normal in primary hyperparathyroidism.

Several indications for surgery exist including:

- Calcium more than1 mg/dl above upper normal limit
- Greater than 30% decline in renal function
- Renal stones
- Age less than 50
- Unwillingness of patient to follow advice of medical surveillance.

Myeloma is unlikely given the normal immunoglobulins.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 28 mins 53 secs

Question: 46 of 100

These are the blood gas results obtained from a 20-year-old female admitted to hospital.

Hydrogen ion concentration	35 nmol/l	(35-45)
pH	7.45	(7.36-7.44)
pCO_2	6.8 kPa	(4.7-6.0)
Bicarbonate	32 mmol/l	(20-28)

Which of the following is the most likely cause of this patient's acid-base derangement?

(Please select 1 option)

- Amitriptyline overdose
- Cushing's syndrome
- Hepatic failure
- Pregnancy
- Salicylate poisoning

Submit answer | Skip question | Tag Question | Remove question

Hydrogen ion concentration	35 nmol/l	(35-45)
pH	7.45	(7.36-7.44)
pCO_2	6.8 kPa	(4.7-6.0)
Bicarbonate	32 mmol/l	(20-28)

Which of the following is the most likely cause of this patient's acid-base derangement?

(Please select 1 option)

- ○ Amitriptyline overdose
- ○ Cushing's syndrome
- ○ Hepatic failure
- ◉ Pregnancy ✓ Correct
- ○ Salicylate poisoning

This patient has a mild metabolic alkalosis with what appears to be respiratory compensation as reflected by the elevated pCO_2.

Amitriptyline overdose is associated with acidosis as is salicylate poisoning.

Hepatic failure usually presents with acidosis.

This type of picture is associated with prolonged vomiting (as in pregnancy), diarrhoea, diuretic therapy and in Cushing's syndrome, or in those receiving high dose corticosteroids. With no other information provided for this case, common things being common, one should select pregnancy as the best answer for a 20-year-old female.

Next question | Tag Question | Remove question

Question: 47 of 100

An 80-year-old male presents with a brief history of weakness and giddiness following an episode of diarrhoea.

He has been taking bendroflumethiazide for the last three years.

On examination his pulse is 100 beats per minute with a blood pressure of 130/80 mmHg (lying) and 100/70 mmHg (standing).

Investigations reveal:

Sodium	120 mmol/L (137-144)
Potassium	5.5 mmol/L (3.5-4.9)
Urea	13 mmol/L (2.5-7.5)
Creatinine	130 µmol/L (60-110)
Random plasma glucose	13 mmol/L (<11.1)

What is the most likely cause of the hyponatraemia?

(Please select 1 option)

- ○ Bendroflumethiazide
- ○ Diarrhoea
- ○ Hyperglycaemia
- ○ Inappropriate secretion of antidiuretic hormone
- ○ Renal tubular acidosis

Random plasma glucose	13 mmol/L (<11.1)

What is the most likely cause of the hyponatraemia?

(Please select 1 option)

- Bendroflumethiazide
- Diarrhoea
- Hyperglycaemia
- Inappropriate secretion of antidiuretic hormone
- Renal tubular acidosis ✓ Correct

The patient has diabetes as reflected by the elevated random glucose, has hyponatraemia, renal impairment and mild hyperkalaemia which appears to have been precipitated following diarrhoea.

Hypoadrenalism is unlikely as he has hyperglycaemia and the hyperglycaemia would itself be expected to cause a dehydration and hence hypernatraemia.

This sort of picture in an elderly male with diabetes is typical of hyporeninaemic hypoaldosteronsim - type IV RTA - and could be exacerbated both by the diarrhoea and by the diuretic.

It is unlikely that the diarrhoea alone has caused the hyponatraemia.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 32 mins 42 secs

Question: 48 of 100

You have been called to the ward by the senior nurse, to review a repeat calcium result. The repeat result is 3.9 mmol/l (2.2-2.6), the previous result four hours earlier was 3.2.

The patient has a disseminated malignancy with an unknown primary.

Which of the following statements is most correct when considering the hypercalcaemia of malignancy?

(Please select 1 option)

- A prolonged QT interval is associated with hypercalcaemia
- Bisphosphonates inhibit osteoblast function thereby lowering calcium
- Calcitonin is of greater benefit than bisphosphonates in the treatment of hypercalcaemia of malignancy
- NSAIDs are indicated for bone pain in this patient
- On neurological examination, hyporeflexia may be exhibited

Submit answer | Skip question | Remove Tag | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

The patient has a disseminated malignancy with an unknown primary.

Which of the following statements is most correct when considering the hypercalcaemia of malignancy?

(Please select 1 option)

○	A prolonged QT interval is associated with hypercalcaemia
○	Bisphosphonates inhibit osteoblast function thereby lowering calcium
◉	Calcitonin is of greater benefit than bisphosphonates in the treatment of hypercalcaemia of malignancy ✕ Incorrect answer selected
○	NSAIDs are indicated for bone pain in this patient
○	On neurological examination, hyporeflexia may be exhibited ← This is the correct answer

This is an oncological emergency.

Hyporeflexia is a common clinical sign in patients with hypercalcaemia.

Non-steroidal anti-inflammatory drugs (NSAIDs) should not be prescribed in patients with hypercalcaemia as they reduce renal blood flow thus inhibiting urinary calcium excretion.

Bisphosphonates inhibit bone resorption by osteoclasts, and are the first line pharmacological treatment of hypercalcaemia of malignancy; calcitonin use is limited by its association with anaphylaxis.

Electrocardiogram changes in hypercalcaemia include bradycardia, prolonged PR interval, short QT interval, widened T waves and arrhythmias.

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 38 mins 42 secs

Question: 49 of 100

Which of the following statements concerning transferrin is correct?

(Please select 1 option)

- In the absence of anaemia transferrin is 80% saturated with iron
- Levels are elevated in haemochromatosis
- Levels are elevated in patients on the oral contraceptive pill
- Transferrin binds ferrous iron
- Transferrin levels fall during pregnancy

Submit answer | Skip question | Tag Question | Remove question

Work Smart Session - MRCP Part 1

Time taken: 1 hrs 39 mins 37 secs

Question: 49 of 100

Which of the following statements concerning transferrin is correct?

(Please select 1 option)

○	In the absence of anaemia transferrin is 80% saturated with iron
○	Levels are elevated in haemochromatosis
◉	Levels are elevated in patients on the oral contraceptive pill ✓ Correct
○	Transferrin binds ferrous iron
○	Transferrin levels fall during pregnancy

Pregnancy and the oral contraceptive pill (OCP) both increase transferrin levels. Iron is carried in the blood bound to transferrin. Fe^{2+} (ferrous iron) is oxidised to Fe^{3+} (ferric iron) by caeruloplasmin to bind to transferrin which is about one third saturated with iron.

The saturation of transferrin (plasma iron concentration/TIBC x 100) is used as a measure of iron stores. A value below 16% is indicative of iron deficiency.

The transferrin level and the TIBC rise in iron deficiency. Pregnancy and the OCP both increase transferrin levels; whereas transferrin and TIBC fall in iron overload, percentage saturation is increased in haemochromatosis.

Corrected calcium	2.72 mmol/L (2.2-2.6)
Phosphate	0.80 mmol/L (0.8-1.4)
Alkaline phosphatase	110 U/L (45-105)
PTH concentration	5.1 pmol/L (0.9-5.4)

What is the most likely diagnosis?

(Please select 1 option)

- (●) Bony metastases ✗ Incorrect answer selected
- ( ) Chronic vitamin D excess
- ( ) Ectopic PTH related peptide (PTHrp) secretion
- ( ) Multiple myeloma
- ( ) Primary hyperparathyroidism ← This is the correct answer

This patient has hypercalcaemia with a borderline low phosphate concentration but an inappropriately normal parathyroid hormone (PTH) concentration.

This suggests hyperparathyroidism, which is a relatively common disorder amongst elderly females.

The story of the breast lump in this case is endeavouring to throw the candidate.

Vitamin D excess would be expected to cause an elevated phosphate.

Question: 50 of 100

A 40-year-old female who has been prescribed thyroid replacement therapy has routine thyroid function tests.

On examination she appeared clinically euthyroid with no abnormal findings.

Her thyroid function tests revealed:

TSH	3.2 mU/L (0.4-5.0)
Total T_4	20 nmol/L (55-144)
Free T_4	2.6 pmol/L (10-22)
Total T_3	2.5 nmol/L (0.9-2.8)

Which one of the following statements is correct?

(Please select 1 option)

- Her thyroid hormone replacement is adequate
- Investigation of pituitary function is required
- She has a thyroiditis
- She has sick euthyroid syndrome
- She has tertiary hypothyroidism

OK

Which one of the following statements is correct?

(Please select 1 option)

○	Her thyroid hormone replacement is adequate ← This is the correct answer
○	Investigation of pituitary function is required
◉	She has a thyroiditis ✕ Incorrect answer selected
○	She has sick euthyroid syndrome
○	She has tertiary hypothyroidism

This question is extremely poorly presented as no one, except for the RCP, measures total thyroid hormone concentrations.

However, this patient has normal TSH, low total T_4 with normal total T_3 and really low free T_4 which would suggest that she is taking T3 as replacement therapy. This may explain why no fT_3 figures are provided.

Consequently she is receiving adequate replacement as reflected by the normal thyroid-stimulating hormone (TSH).

She does not have sick euthyroidism as it states in the run in that these measurements were routine. Although TSH is normal and tT_4 and fT_4 low, secondary/tertiary hypothyroidism would not explain the plum normal total T_3 concentration.

She may well have had a thyroiditis such as Hashimoto's to have given her the hypothyroidism originally but she is now on replacement therapy and the former would not explain her thyroid function tests.

Work Smart Session - MRCP Part 1

Time taken: 2 hrs 1 mins 40 secs

Question: 51 of 100

Which of the following cell types are linked with the substance they synthesise ?

(Please select 1 option)

○	Gastric chief cells - intrinsic factor
○	Islet A cells - somatostatin
◉	Islet B cells - amylin ✓ Correct
○	Islet D cells - pancreatic polypeptide
○	Islet F cells - glucagon

Islet beta cells produce insulin and amylin, as well as C-peptide, pro-insulin and gamma-aminobutyric acid (GABA).

- Islet D cells produce somatostatin
- F cells produce pancreatic polypeptide and
- A cells produce glucagon
- Gastric chief cells produce pepsinogen whilst
- Gastric parietal cells produce acid and intrinsic factor.

Time taken: 2 hrs 1 mins 40 secs

Question: 52 of 100

A patient with type 1 diabetes displays typical symptoms of hypoglycaemic unawareness.

Which of the following statements regarding hypoglycaemic unawareness is correct?

(Please select 1 option)

○	Alcohol inhibits gluconeogenesis in patients with hypoglycaemia unawareness
○	Glucose sensing occurs in the locus caeruleus
○	Recurrent hypoglycaemia has no long term consequences on higher cerebral function
○	Recurrent hypoglycaemia is most commonly associated with poor diabetic control
○	Selective beta-blockers are an important cause of hypoglycaemia unawareness

Submit answer | Skip question | Tag Question | Remove question

© 2011 BMJ Publishing Group Ltd . All rights reserved . Terms and conditions . Privacy policy . A A A

Question: 52 of 100

A patient with type 1 diabetes displays typical symptoms of hypoglycaemic unawareness.

Which of the following statements regarding hypoglycaemic unawareness is correct?

(Please select 1 option)

◉	Alcohol inhibits gluconeogenesis in patients with hypoglycaemia unawareness ✓ Correct
○	Glucose sensing occurs in the locus caeruleus
○	Recurrent hypoglycaemia has no long term consequences on higher cerebral function
○	Recurrent hypoglycaemia is most commonly associated with poor diabetic control
○	Selective beta-blockers are an important cause of hypoglycaemia unawareness

Alcohol

- Inhibits gluconeogenesis
- Decreases peripheral hypoglycaemic responses and
- Impairs perception of symptoms of hypoglycaemia.

There is no evidence to suggest that beta-blockers cause hypoglycaemic unawareness.

Glucose sensing occurs in the hypothalamus, and there is evidence to suggest that chronic, and recurrent hypoglycaemia may have deleterious effects on higher cerebral function.

Question: 53 of 100

Which of the following is not a feature of zinc deficiency?

(Please select 1 option)

○	Dwarfism
○	Geophagia
○	Hepatosplenomegaly
◉	Hypertelorism ✓ Correct
○	Hypogonadism

Zinc deficiency is associated with

- Dwarfism
- Hypogonadism
- Hepatosplenomegaly
- Rough and dry skin
- Mental lethargy and
- Geophagia.

Zinc supplementation has also been shown to improve neuropsychological function in Chinese children, and zinc deficiency is associated with adverse pregnancy outcomes.
